

For better maintainability and agility, a management plane is separated from the control plane, and observability operations like monitoring and auditing are taken to the management plane. For example, in Azure, Azure Resource Manager (ARM) operations are termed as management plane activities.

This kind of resource management through control plane, data plane and management plane helps to control and manage security services, auditing, policy driven activities, activity logs and resource hierarchy services.

Similarly, in the AWS platform, Elastic Kubernetes Service (EKS) extension is a service connector, which helps to connect EKS or Fargate with monitoring, security, observability and governance tools. Extension connectors are available for popular instrumentation and log analysis tools like Lightrun and also native services like CloudWatch Lambda Insights and AppConfig.

Deploying an EKS instance with Lightrun agent for logging and monitoring

Elastic Kubernetes Service (EKS) with Lightrun extension can be run in two modes – internal and external.

- The internal EKS extension process attaches as an instrumentation thread, as in-process to runtime, and enables automatic instrumentation for code.
- The external EKS extension process runs outside the application runtime and can be invoked or shutdown manually.
