

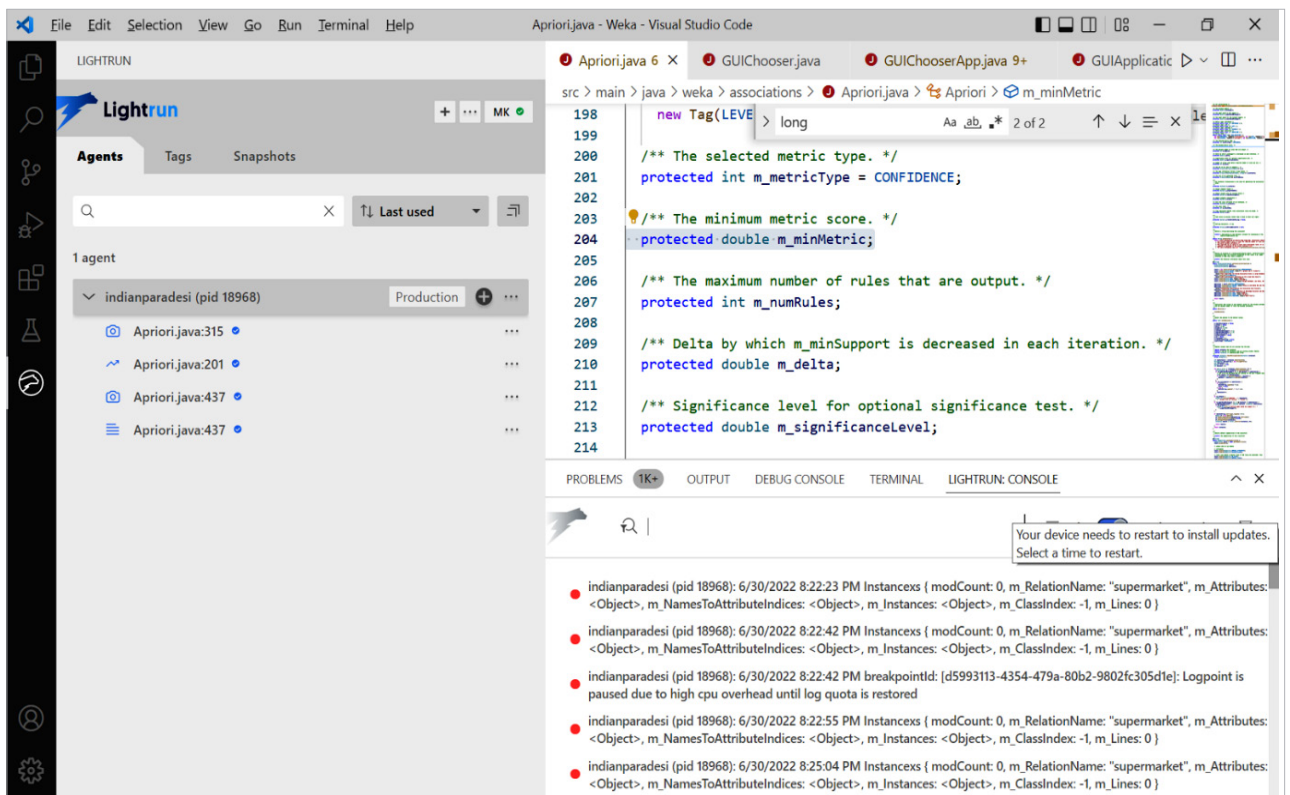

Figure 6: Lightrun agent configured with log, snapshot and metrics

We can make use of Lightrun for improved debugging and application engineering activities like monitoring, management, logging and metrics collection of dynamically running containers. For example, if there is trouble making a piece of code in a function or event, we can add a snapshot to that line of code. When there is a call to that line of code, snapshot gets captured dynamically and can be used offline to understand the stack of call tree and analyse the flow of call.

We can also add dynamic logging or dynamic metrics in the form of expression or evaluation variables so that regular monitoring of these variables (in terms of change of value or change of expression at different intervals of the runtime) can be done and analysed to debug a particular flow of the application component.

For the above example of running an EKS instance with Java containers on a Spring Boot application, I have taken the open source Weka application (data mining application) and deployed it using Kubectl.

Lightrun simplifies operational activities in site reliability engineering (SRE) to reduce the L2 and L3

activities of production support. It also integrates native monitoring and management for development teams using integrated native observability patterns. Dynamic log configuration reduces the overall log size and flexibly debugs the containers without re-creating the container image with additional code. **END** 🐧
