

Canonical launches MicroCloud

Canonical has introduced MicroCloud, a game-changer in cloud computing designed for scalable clusters and edge deployments. MicroCloud prioritises simplicity, security, and automation, allowing businesses to deploy a fully functional cloud solution with a single command, minimising deployment time.

Security takes centre stage as MicroCloud ensures strict confinement and over-the-air transactional updates for data integrity. The solution offers flexibility, supporting deployment on-premise or at the edge, providing a consistent experience regardless of location.

Cédric Gégout, VP of product at Canonical, highlighted MicroCloud's response to the evolving cloud landscape: "As data becomes more distributed, the infrastructure has to follow. MicroCloud is our answer to that, delivering a simpler, more prescriptive cloud experience that makes zero-ops a reality."

MicroCloud is versatile, running on both commodity and high-end hardware, and is compatible with Ubuntu Desktop, Server, and Core. Workloads can be executed using Kubernetes or system containers, ensuring efficiency with reduced resource consumption.

Offered within Canonical's Ubuntu Pro subscription, MicroCloud provides users with an enterprise-grade, open source solution supported by different tiers. It adopts a transparent per-node pricing model, eliminating hidden fees.

The most pressing issue addressed by WordPress 6.4.1 was a critical bug that caused users to encounter download failures, displaying a disheartening error message - "cURL error 28: Operation timed out." The root of this problem can be traced back to a major change in WordPress 6.4, specifically an update to the Requests library version. This update included a breaking change for users on hosts with cURL version 7.29 or older, which was, unfortunately, more common than expected. The latest cURL version is 8.4.0, highlighting the need to stay up to date.

Another critical issue stemmed from the removal of code that was no longer used by the WordPress core, an action taken in an attempt to streamline and optimise the platform. However, the removal of this code inadvertently disrupted various plugins that still relied on it. The consequences were far-reaching, causing issues for users and their websites. The solution provided by WordPress 6.4.1 was to reintegrate the removed code, ensuring that backward compatibility was maintained and that plugins could function without hiccups.

The final issue tackled by this maintenance release was relatively minor in comparison but still noticeable. A typographical error affected the appearance of a nag screen in the administrator panel, causing it to stretch awkwardly across the top of the page. This typo was rectified with the release of WordPress 6.4.1.

India's developer community surges; eyes 2027 crown

India's developer community is booming, with a remarkable addition of 3.5 million developers in 2023, bringing the total to an impressive 13.2 million. GitHub's 2023 State of the Octoverse report predicts that by 2027, India could overtake the United

States, becoming the world's largest developer hub. This significant growth is not just numerical but is substantiated by India's contributions to open source projects.

The report highlights a 36% increase in India's

developer community in 2023, demonstrating its consistent upward trajectory. Moreover, India plays a pivotal role in collaborating with the UN-backed Digital Public Goods Alliance, contributing to the development of a digital public infrastructure encompassing software and AI models.

The report underscores the global surge in individual contributors to generative AI projects, showcasing 148 percent year-over-year growth. Besides India, the United States and Germany stand out as leaders in developer communities, with Japan, Hong Kong, the United Kingdom, and France following closely behind.

MikroElektronika unveils ClickID

MikroElektronika (MIKROE) has introduced ClickID, a hardware/software open source solution that aims to transform the landscape of embedded development. Based on a one-wire device, it enables effortless hot-plugging of Click or any mikroBUS-compatible add-on peripheral boards into development boards running embedded Linux or similar operating systems.

ClickID eliminates the need for manual configurations at boot-time. According to Nebojsa Matic, MIKROE's CEO, "ClickID brings a new level of automation and self-diagnosis to embedded tools. We have eliminated the challenge of configuring devices at boot-time with device trees, which is time-consuming and error-prone."
