

Rajan Anandan tweets in response to Sam Altman's unthoughtful reply when asked if a startup from India can create something like ChatGPT (Source: @RajanAnandan)

that a smart scammer can easily bypass these. After all, when you make a scam call, you are not going to speak foul language or malicious content. It is going to be as normal a conversation as can be! So, how effective would these checks be?

In a very interesting post titled *Chatbots, deepfakes, and voice clones: AI deception for sale*, Michael Atleson, Attorney, FTC Division of Advertising Practices, asks companies to think twice before they create any kind of AI-based synthesising tool. "If you develop or offer a synthetic media or generative AI product, consider at the design stage and thereafter the reasonably foreseeable—and often obvious—ways it could be misused for fraud or cause other harm. Then ask yourself whether such risks are high enough that you should not offer the product at all. It has become a meme, but here we will paraphrase Dr Ian Malcolm, the Jeff Goldblum character in *Jurassic Park*, who admonished executives for being

so preoccupied with whether they could build something that they did not stop to think if they should."

Who wrote that assignment?

AI is turning out to be a headache for educational institutions too! In a recent survey of 1,000 university students conducted by Intelligent.com, 30% admitted to using ChatGPT to complete their written assignments! If this goes on, we will end up with professionals who do not know their job. No wonder, universities across the world are exploring ways and means to curtail the use of ChatGPT to complete assignments.

Startups like Winston AI, Content at Scale, and Turnitin are offering subscription-based AI tools that can help teachers detect AI involvement in work submitted by students. Teachers can quickly run their students' work through a web-based tool, and receive a score that grades the probability of AI involvement in the assignment.

Experts believe that there are always a few clues that give away AI-generated content, such as the overuse of the article 'the,' absolute lack of typos and spelling errors, a clean and predictable style quite unlike how humans would write, and so on. Large language models can be used to detect AI-generated content, by retraining them using human-created content and machine-generated content, and teaching them to differentiate between the two. Once more a case of AI helping counter an evil of AI!

The problem does not end with students making AI do assignments. It is about morality. In the real world, it leads to problems like misinformation and copyright infringement. And when such issues arise, people do not even know whom to sue!

Take the case of image generation with AI. It is now possible to create life-like images using AI platforms like Midjourney. While this creates a slew of opportunities for various industries such as advertising and video game production, it also leads to varied issues, including piracy and privacy. Usually, in the case of an image, the copyright rests with the human artist. When an AI platform creates the image, whom does the copyright rest with? And suppose the image infringes on someone else's copyright, whom will the artist sue? In one of his articles in mainstream media, Anshul Rustaggi, Founder, Totality Corp., alerts that with AI generating hyper-realistic images and deep fakes, businesses must address the risks of misuse, personal privacy infringements, and the spread of disinformation. He further adds that distinguishing between real and AI-generated content could become increasingly challenging, creating potential avenues for misinformation and manipulation.

In April this year, members of the European Parliament agreed to push the draft of the AI Act to the trilogue stage, wherein EU lawmakers and
