

The Incentivised Testnet serves as a crucial step in the tea Protocol's journey toward a robust mainnet on the Base blockchain. This testing phase ensures the network's efficiency, security, and overall success.

Key features

of the Incentivised Testnet include a waitlist offering limited opportunities, detailed insights into \$TEA tokenomics, comprehensive documentation access, teaRank for project visibility, and tea points accumulation for both developers and non-developers.

Joining the Incentivised Testnet provides an opportunity to be part of a pioneering movement in open source software, engaging with a forward-thinking community and understanding tea's tokenomics.

China shifts to open source chips amid rising US export controls

China is strategically embracing open source chips, notably the RISC-V architecture, as the US tightens export controls on advanced semiconductors. The People's Liberation Army's (PLA) Academy of Military Sciences recently patented a high-performance chip, showcasing China's bid to reshape the global chip market and withstand US sanctions.

RISC-V, an open source standard, is becoming integral to Beijing's plan to reduce reliance on Western technology. The architecture, though a fraction of the chip market, offers geopolitical neutrality, noted the Shanghai government's Science and Technology Commission.

Investments in RISC-V by Beijing and sanctioned entities have surpassed \$50 million between 2018 and 2023, fostering breakthroughs in applications like self-driving cars and data storage centres. While ARM dominates the Chinese market, RISC-V is emerging as a strategic bet, with the performance gap narrowing.

China's military involvement in RISC-V is evident, with research institutes linked to the PLA actively promoting the architecture. State-owned Dongfeng

Motor Corporation successfully developed an automotive MCU chip using RISC-V, demonstrating its versatility.

China's measured investment in RISC-V underscores its commitment to establishing technological self-sufficiency, navigating

around potential export restrictions. The move reflects a calculated strategy, as China positions itself in the evolving landscape of global chip development.

Meta plans AI strategy around three key pillars

Mark Zuckerberg has unveiled Meta's core AI strategy during the Q4 2023 earnings call, shedding light on three key pillars: formidable compute infrastructure, a steadfast commitment to open source, and access to an extensive pool of training data from Facebook and Instagram.

Zuckerberg highlighted the pivotal role of compute power, stating, "Our long-term playbook is to become leaders in building the most advanced AI products and services, as well as building the full general intelligence." The company is set to possess around 600k H100 equivalents of compute by year-end, a result of lessons learned from Instagram Reels development.

Addressing Meta's open source approach, despite recent criticism, Zuckerberg emphasised its strategic benefits. "Open source software is typically safer and more secure, as well as more compute efficient to operate," he remarked, underlining its role in fostering industry standards and attracting top talent.

The vast training data at Meta's disposal was a focal point, with Zuckerberg revealing "hundreds of billions of publicly shared images and tens of billions of public videos" on Facebook and Instagram. This data, he asserted, surpasses the Common Crawl dataset, complemented by "large numbers of public text posts in comments across our services."

Zuckerberg concluded with Meta's proactive stance in the AI race, stating, "We are playing to win." The company's commitment is evident through aggressive investments in AI infrastructure, hinting at significant capital expenditure in 2024.
