

Figure 4: Identity management

implementation of the Lightweight Directory Access Protocol (LDAP), developed by the OpenLDAP Project. Active Directory (or AD) is a directory service created by Microsoft for Windows domain networks and is included in most Windows Server operating systems.

Administrators can set up a separate identity provider (IdP) using either OpenAM, ADFS or any other open source IAM product. The use of the cloud manager component provided by private cloud products helps XYZ Market set the OpenAM IdP as the identity provider for it. Thereafter, when users from XYZ log in to their organisation's private cloud, they will be redirected

to OpenAM, where they can be authenticated and be directed back to the cloud portal.

Advantages

- Secure access to private cloud infrastructure
- No need for XYZ to create its own user identities in order to participate in the management process, which would increase the administrative overhead

Deleting a document

To delete a document, you need to use the `remove()` method:

```
<?php
// connect to mongodb
$m = new MongoClient();
echo "Connection to database successfully";
// select a database
$db = $m->mydb;
echo "Database mydb selected";
$collection = $db->mycol;
echo "Collection selected successfully";

// now remove the document
$collection->remove(array("title">"MongoDB
Implementation"), false);
echo "Documents deleted successfully";

// now display the available documents
$cursor = $collection->find();
// iterate cursor to display title of documents
echo "Updated document";
```

```
foreach ($cursor as $document) {
    echo $document["title"] . "\n";
}
?>
```

When the above program is executed, it will produce the following result:

```
Connection to database successfully
Database mydb selected
Collection selected successfully
Documents deleted successfully 
```
