installed globally, and can be executed from any folder on the computer.

Next, let us create a sample project and start configuring it. It is important to understand the folder structure first. To keep this example simple, let's not include a lot of files. I've created a project named 'GruntTest' and in it I have two folders - 'src' and 'build'. The 'src' will contain the original source code and the build folder will contain all the files that are to be released as a build. Or in other words, the build folder will contain files after performing any 'grunt' tasks on the source files. Next, at the project level, I have two more files called 'package.json' and 'Gruntfile.js'. My 'src' folder contains a single script file called 'GruntTestScriptFile.js'. This entire folder structure can be seen in Figure 1. The folder structure can be kept in whichever way the user desires, but it is important to ensure the placement of 'package.json' and 'Gruntfile.js' in the root directory of the project.

Now let us understand what 'package.json' and 'Gruntfile.js' are. The package.json file is a feature of Node.js. Simply put, package.json is used by the npm to store the metadata for projects. This project is thus treated as an

npm module. All dependencies required for any npm module are mentioned in the package.json file. Hence, we are going to mention 'grunt' and any grunt plugin that we are going to use in the 'package.json' file. It is important to note here that package.json should be a JSON and not a JavaScript object literal. To read more about package.json, you can visit: <https://npmjs.org/doc/json.html>. There are many ways to create the package.json file. One automated way is to simply execute npm init at the root directory of the project. This will help you to create a package.json file without having to explicitly type everything. But for beginners, this can be a tough task. For our project, let us go ahead and create a simple package.json file:

```

{
  "name": "GruntTest",
  "version": "0.1.0",
  "devDependencies": {
    "grunt": "~0.4.1",
    "grunt-contrib-uglify": "~0.2.2"
  }
}

```

Given above is the entire code for the package.json file. The 'name' key is the name of the project. The 'version' is the current build version. The 'devDependencies' are the
