

Download the latest version <https://ghost.org/download/> and extract it to a folder named 'ghost'. But if you have a terminal opening right in front of you, then the following commands will do the trick:

```
curl -L https://ghost.org/zip/ghost-latest.zip
-o ghost.zip
unzip -uo ghost.zip -d ghost
```

Now `cd` to the folder named 'ghost' that you created earlier. `cd` to the correct folder and run the `npm` commands as follows:

```
cd path/to/ghost
```

In my case it was in the *Downloads* folder:

```
cd Downloads/ghost
```

Then install Ghost with:

```
npm install -- production
```

After installation, type the following command to start Ghost:

```
npm start
```

Mac and Windows users can refer to the respective documentation for installation instructions (<http://docs.ghost.org/installation/>). Ghost will be up and running on Port number 2368. Point your browser to <http://127.0.0.1:2368/> to see your Ghost blog in action. Now it's time to create an admin user. Change the URL to <http://127.0.0.1:2368/ghost>, and create your admin user to log in to the Ghost admin.

For now, Ghost allows only one user per blog; multi-user support will be available in version 0.5, which is expected to be out early in July 2014. If you still want multiple user support, there are some hacks available like the one at <http://lifewiththetacks.com/multi-user-support/>. After signing in successfully, you may encounter a warning related to email configuration, which you can leave for now, as it will be used for resetting the password.

Writing

Writing a post in Ghost is simple. When you install it, there already is a post made for you which explains everything about writing. To put it simply, the writing is done in Markdown format.

Theming and customisation

Theming and customisation are simple and straightforward. To add a new theme, just copy the folder that has theme files to the *Themes* folder, which is inside the *Content* folder section and update the theme in the dashboard. Here is an example of the

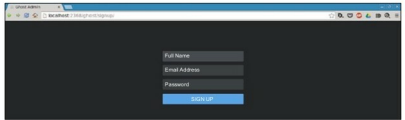

Figure 1: Ghost sign-up page

Figure 2: Dashboard theme section

installation of a new theme named Froyo, which is available at <https://github.com/adriannorman/froyo-ghost-theme>. Download the zip file and extract it to `ghost_folder -> content -> themes` and restart Ghost. You can browse the themes at marketplace.ghost.org and then update them in the dashboard by navigating to `/ghost/settings/general/`.

Deployment

Now we are ready with a blog and, hopefully, can begin writing some interesting posts. But how do we share them? We can't host our blog on our computer because of security reasons and also considering the fact that electricity is not cheap. So we need to deploy our Ghost blog, for which we have many options. But for now, we are interested only in free options, with custom domains also for free. This brings our options down to two places: OpenShift and Github pages.

OpenShift

OpenShift allows easy deployment of Ghost blogs. Before getting started, get an account on OpenShift and install the necessary tools from <https://www.openshift.com/developers/rhc-client-tools-install>. To create the app, type the following command:

```
rhc app create ghost nodejs-0.10 --env NODE_ENV=production
--from-code https://github.com/openshift-quickstart/openshift-ghost-quickstart.git
```

...or follow the guide available at <https://www.openshift.com/quickstarts/ghost-on-openshift>. Whenever you want to add a new theme or edit some configuration, use the following command:
