

How to Configure Ubuntu as a Router

Did you know that your Ubuntu system could be configured to act as an immensely powerful router? Surprised? Read on to discover how to achieve this with just a few simple steps.

If you have two network interface cards installed in your Ubuntu system, one of which connects you to the Internet and the other to a local network, then your system can be transformed into an immensely powerful router. You can establish basic NAT (Network Address Translation), activate port forwarding, form a proxy, and prioritise traffic to and from your system so that your downloading does not interfere with your gaming. This article describes how to set up your Ubuntu system as a router, which can later be configured as a firewall. It requires prior knowledge of 'iptables'. The resulting set-up will help you to control traffic over ports and make your system less vulnerable to security breaches.

Gateway set-up

The pre-requisites to setting up a gateway are:

- A computer with Ubuntu OS
- Two network cards
- Internet connectivity
- Knowledge of iptables

Two network cards will have to be installed in the computer. One connects to the Internet, which we will call eth1. The other connects to our internal network.

We will call this card eth0.

Host A (192.168.1.8) ==> Eth1 ==> Ubuntu Gateway ==> Eth0 ==>
Host B (10.10.6.205)
