

India-based start-up launches maiden Linux container-sharing website

Flockport, a start-up based in Mumbai, announced the launch of Flockport.com, which is the first Linux container (LXC) sharing website that will offer users popular Web applications in portable containers. Users will get cloud-like flexibility of application instances, which can be deployed on demand. Users and developers accessing this website will be able to download and share LXC containers; a Flockport Utility will also be provided to set up LXC for users, who will be allowed to view and download Flockport containers directly to their systems. A fast improving technology, Linux containers provides all the benefits of virtualisation without any performance penalty. Containers are portable and they can be cloned, backed up, launched and also deployed across environments. This opens up a world of flexibility for application developers and users. Unlike preceding container technology, Linux containers pave the way for widespread adoption. There is a significant information gap on LXC in the marketplace, which has to be addressed by Flockport. This is a free service and users will also be allowed to deploy containers directly to the cloud. This will help public cloud providers broaden their market base by allowing customers to deploy complex applications in seconds.

Mozilla has provided long-term support to Online Certificate Status Protocol (OCSP), which is used to check with a CA on the status of a given certificate. OCSP Stapling, an extension of OCSP, accelerates the SSL certificate status-checking process. Moreover, to improve security, Firefox 32 doesn't contain a number of 1,024-bit trust certificates from the browser. Additionally, Mozilla has also issued six security advisories for vulnerabilities. Three of them are quite critical. Details of the memory-corruption vulnerabilities have been provided by the Mozilla Foundation Security Advisory (MFSA) 2014-67. A researcher who has been working with Hewlett-Packard's Tipping Point Zero Day Initiative (ZDI) has been credited with reporting a use-after-free memory issue (identified as MFSA 2014-72). This, in particular, was caused by setting the direction of text on a page.

Chrome 38 brings a new responsive image element called 'Picture'

The pictures and photographs on websites, known as simple images, are all static images. But Google's Chrome 38 is set to change this old concept with a new responsive element called 'Picture'. This would introduce a new responsive design to the website, which renders and scales the elements on the Web page in the appropriate format for the screen size. HTML 5.1 has replaced image tag with the superset element for image containers. Google's 'Picture' element is based on this technology in W3C HTML 5.1. Some Linux distributions like Ubuntu, Fedora, openSUSE, Debian and Red Hat already have 64-bit beta channel support but for the Mac, this will be the first browser to provide a 64-bit build. Currently, Mac users can run the Canary branch of Chrome to get a 64-bit version of Chrome. This new 64-bit build of Chrome for the Mac should bring the most stable and usable Web browser to the Mac platform. The Chrome 37 64-bit build for Windows is supposed to release in the same week.

CoreOS announces free availability of its Docker-focused Linux distribution

Last year, Docker emerged as one of the most discussed virtualisation technologies. But running Docker requires much effort. CoreOS has announced that its Docker-focused Linux distribution is now available for free as an image that can be deployed on the popular DigitalOcean cloud service. It also lowers the barrier to entry, and the cost for setting up the Docker and running it.
