

```
</html>
```

Jinja2 supports control and loop structures in the template by using flowerbraces `{{ }}`. *base.html* is the basic layout for our Web application. Other pages can simply extend this page and the rest of the operations will be handled by Jinja2.

index.html

```
{% extends "base.html" %}
{% block content %}
<h1>Welcome to my app</h1>
{% endblock %}
```

The Jinja2 template allows inheritance, and the *index* file inherits the basic layout from *base.html*.

about.html

```
{% extends "base.html" %}

{% block content %}
<p>This is about page of flask</p>
{% endblock %}
```

posts.html

```
{% extends "base.html" %}

{% block content %}
{% for post in posts %}
<div class="title">
<h2>{{post.title}} </h2>
</div>
<div class="content">
<p>{{post.body}}</p>
</div>
{% endfor %}
{% endblock %}
```

In *manage.py*, the content for the post page is passed using the *render_template* method and can be identified using its key.

style.css

```
a {
text-decoration: none;
}

header {

padding : 2px;
margin-left: 50px;
```

```
margin-top: 10px;
width : 130px ;
height: 70px;
border-radius: 5px;
background-color: #C2BABC;
}

ul li{
list-style: none;
display: inline;
float: right;
padding: 10px;
}

ul li a{
background-color: #2E2E2E;
color :#FFF;

border-radius: 3px;
}

.container {
margin-top: 20px;
margin-left: 70px;
width: 500px;
}

.title {
background-color:#C2BABC;
}
```

Creating Web applications using Flask is very simple and needs little or no experience, when compared to other languages. The server part will be handled by Flask, and no extra server setup is needed. Flask is known for its simplicity. The core API is simple and is based on the Jinja2 template engine and the Werkzeug WSGI toolkit. It allows developers to choose their own third party Python packages depending on their interests. Using Flask is a good option for complex Web applications. It makes the applications easy to understand and enables developers to work on different modules efficiently.
