

IBM Worklight

A Mobile App Development Platform

IBM Worklight offers cross-platform portability of the application code, which is crucial during apps development.

Worklight enables the development of rich HTML 5 and hybrid apps using native code.

IBM Worklight provides an open, comprehensive and advanced mobile app development platform for smartphones and tablets. It can be used to create all kinds of native, Web-based or hybrid mobile apps very easily. It includes the IBM Worklight Studio—an Eclipse-based IDE (integrated development environment) in which all the coding and integration tasks are performed to develop a fully functional mobile app.

IBM Worklight consists of five main components as shown in Figure 1.

Worklight Studio

This is one of the leading tools for cross-platform, hybrid development that maximises code reuse and enables per-device optimisation. You can make apps for Android devices, the BlackBerry or other devices.

Worklight Application Centre

The Worklight Application Centre enables companies to easily set up an app store for their enterprise and development teams.

The application centre provides:

- Administrators with fine-grained control over the distribution of mobile apps across the enterprise,

including ACL and LDAP support;

- Employees with a central location for the latest apps needed by their department and optimised for their device;
- Developers with an easy way to distribute mobile builds and elicit feedback from development and test team members.

Device runtime

Device runtime is client-side runtime code that embeds server functionality within the target environment of deployed apps.

IBM Worklight Server

The Java-based server is a scalable gateway between applications, external services, and the enterprise backend infrastructure. The server contains security features to enable connectivity, multi-source data extraction and manipulation, authentication, the direct update of Web and hybrid apps, analytics and operational management functions.

Worklight Console

This is a Web-based UI that allows application version management (installs, updates, disables and enables), and push management that provides administrative dashboards for
