

Figure 1: Worklight's structure

deployed applications and installs adapters.

I am not going into too many details because a lot of information can be found on the IBM website.

Installing Worklight in Eclipse

Open Eclipse and go to the *Help* tab. Click on it and select *Eclipse marketplace*.

A window will open; search for *worklight* and press *Enter*. You'll find two products related to Worklight as shown in Figure 2.

Click on the *Install* button; it'll check the product and the *Confirm* button will appear. Click on it and the progress bar of the download will be shown. After installation, you will see the *Update* and *Uninstall* buttons; this means you have installed Worklight successfully.

Figure 2: Eclipse marketplace

Figure 3: Android SDK manager

Installing the Android Development Kit (ADK)

Before installation, change the perspective of Eclipse. Go to the *Window* tab --> *Open Perspective* --> *Java*.

After changing the perspective, open the window tab again, and check whether the ADK is there. If not, install the ADK in the same way as we installed Worklight earlier.

After installing the ADK, check the Android SDK manager. Some APIs would have been installed, while some will have to be installed after some time as shown in Figure 3.

Figure 4: Android virtual device manager

Making an Android virtual device

Open the window tab and click on *Android Virtual Device Manager* as shown in Figure 4. When a window opens, press *New* and fill in the details of the device—in this case your Android mobile phone. Next, press *OK*, select your newly created device and press the *Start* button. You will be asked about the real size of the screen/display. Now, press *Launch*. After some time, a beautiful Android screen will come up as shown in Figure 5.

Making and deploying Android apps

Let's start off by creating a Worklight project called *Mohit_Android*. Click *Next* and fill in the application's name, say *mohit_android*, and then press *Finish*. This

opens a screen as shown in Figure 6. While opening the screen, sometimes, it changes the perspective—which means it sets it to 'Java EE' if this was not set yet. You can manually change the perspective.

So we've finished with the setting up, and it's time to make our first app. We are going to make a simple calculator.

Step 1: Given below is the Java script code.
