

Creating Dynamic Web Portals Using Joomla and WordPress

Joomla and WordPress are popular Web content management systems, which provide authoring, collaboration and administration tools designed to allow amateurs to create and manage websites with ease.

Nowadays, every organisation wishes to have an online presence for maximum visibility as well as reach. Industries from across different sectors have their own websites with detailed portfolios so that marketing as well as broadcasting can be integrated very effectively.

Web 2.0 applications are quite popular in the global market. With Web 2.0, the applications developed are fully dynamic so that the website can provide customised results or output to the client. Traditionally, long term core coding, using different programming or scripting languages like CGI PERL, Python, Java, PHP, ASP and many others, has been in vogue. But today excellent applications can be developed within very little time. The major factor behind the implementation of RAD frameworks is re-usability. By making changes to the existing code or by merely reusing the applications, development has now become very fast and easy.

Software frameworks

Software frameworks and content management systems (CMS) are entirely different concepts. In the case of CMSs, the reusable modules, plugins and related components are provided with the source code and all that is required is to only plug in or plug out. The frameworks need to be installed and imported on the host machine and then the functions are called. This means that the framework with different classes and functions needs to

be called by the programmer depending upon the module and feature required in the application. As far as user-friendliness is concerned, the CMSs are very easy to use. CMS products can be used and deployed even by those who do not have very good programming skills.

A framework can be considered as a model, a structure or simply a programming template that provides classes, events and methods to develop an application. Generally, the software framework is a real or conceptual structure of software intended to serve as a support or guide to build something that expands the structure into something useful. The software framework can be seen as a layered structure, indicating which kind of programs can or should be built and the way they interrelate.

Content Management Systems (CMSs)

The digital repositories and CMSs have a lot of feature-overlap, but both systems are unique in terms of their underlying purposes and the functions they fulfill.

A CMS for developing Web applications is an integrated application that is used to create, deploy, manage and store content on Web pages. The Web content includes plain or formatted text, embedded graphics in multiple formats, photos, video, audio as well as the code that can be third party APIs for interaction with the user.
