

Integrating Android with **jQuery** mobile

The jQuery Mobile article in the *OSFY* November issue began with 'Hello PhoneGap', and went on to cover various types of list-views and form elements. This article covers some amazing features that make jQuery Mobile a unique platform—pop-ups, dialogue boxes, tool-bars, transitions and themes.

First, let us continue with form elements and then look at theming our applications.

Form elements—the next batch

Flip or toggle switch: This is a UI element used on various mobile devices. It is also called an On/Off switch and is used for true/false data input. Users can either drag the slider, or tap one side to toggle. To get it, use `data-role="slider"` under the `select` attribute, and two options appear—one option is 'On', and the other 'Off'. Set the `for` attribute of the label to match the `id` of the `select` attribute:

```
<label for="toggle1">Toggle Flip switch:</label>
<select name="Toggle" id="toggle1" data-role="slider">
  <option value="on">On</option>
  <option value="off">Off</option>
</select>
```

Longer labels: To use longer labels like *Switch On/Switch Off*, we need to use a predefined class `.ui-slider-switch` {width: 10em}. You can add this class in a style tag as CSS, and add the class name within the `div` tag as follows:

```
<style>
.toggle-container .ui-slider-switch { width: 10em }
</style>
```

Add the class name as `toggle-container` in the `div` tag, as shown below:

```
<div class="toggle-container">
```

The result of this can be seen in Figure 1.

Mini version: This version is useful for tool-bars, and can be included using `data-mini="true"` inside the `select` tag.
