

CloudBees: Deploying Applications

The article published in the October issue of *OSFY* covered the concept of Platform as a Service, the Java PaaS, an introduction to CloudBees, the ecosystem, and other features. With that as a background, readers are now invited to move on and deploy a simple Web application on CloudBees.

To deploy a Web application, you need to create the database, use the CloudBees Eclipse plug-in to create a CloudBees project, run the application in the local and cloud environment, and understand the Sauce Labs and SonarSource services offered by CloudBees.

Registration

Registration for CloudBees is very easy. You need to provide details such as:

- Username—used to log in to Maven, SVN, and GIT
- Account Name, which will be used to construct the service URL for *DEV@Cloud* (https://app_name.account_name.cloudbees.com/)

Services

Once registration is successfully completed, click *Add Services* on the *Services* menu in the Dashboard (Figure 1) to add services for your account. All information related to a specific service like *Database* or *Run@Cloud* is made available, including the types of service offerings (Figure 2). Click the *Learn More* link for any service and then click *Active* to activate that service, after comparing the features available in the free and on-demand versions.

Using the application service

The on-demand option includes all the configuration features required for enterprise cloud applications. In the

free plan, a maximum of 5 Tomcat or EE applications are allowed. Tomcat and JavaEE apps are free, and an instance will have 128 MB of RAM, besides which user forums are available for support. To know more about *Run@Cloud* pricing, visit <https://grandcentral.cloudbees.com/services/plans/application>.

In the subscribed services list (Figure 3), click *Applications* to deploy an existing WAR file of an application. Click *Add New Application*, give the application name (e.g., *timenexpense*) and select *JVM Web Application* as the *Application Core Runtime*. Once the application is ready, you will be notified; your new application will be available at <http://timenexpense.cleanclouds.cloudbees.net>

Next, click *Configure*. Go to the *Deployments* section (Figure 4), where you will see an *Initial Create* label with a timestamp. Click the *Upload New Version* button; it will open an upload form to deploy a new application version. Click *Browse*; select the appropriate WAR file from your system, provide a description and click *OK*.

Using the database service

CloudBees supports the MySQL database. Database management is typically done using a MySQL client like the *'mysql'* command-line program distributed with MySQL. It provides Apache DBCP connection pool implementation, and supports external databases as well. To connect your application to a non-CloudBees database,
