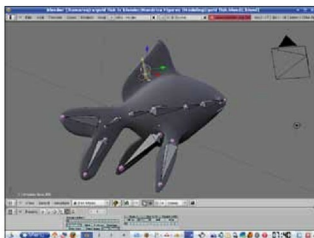

Figure 11: Armature 6

adding an armature, which is basically the first parent bone created. The armature panel provides us many options for setting up our skeleton, including the following for setting up different types of bones and editing them.

- **X-Ray:** It lets you see the armature through anything

in the scene, solid or not. It is useful to know where the bones are in your character, so you can select them.

- **Automatic IK:** This is a *Posemode* option, which lets you pose a chain of bones as if the bone you are holding is an IK target. More information is available in the *Posemode* page.
- **Display options:** These let you visualise bones in various ways. Note that some options and features are specific to the display mode you're in.
- **Octahedron:** This is the default view. There is nothing exciting about it, except that you have a good idea of how the bones in your character move.
- **Stick:** This display mode is really useful when you have a lot of bones in your view. It lets you 'unclutter' the screen a bit, drawing the bones as tiny sticks.
- **B-bones:** This is more a feature than a display mode; it is only useful to visualise the effect you get when you activate the B-bones (Bézier-Bones). Each bone acts like a curve handle, and lets you get extremely curvy poses. This will be exposed in the following pages.
