

KNOW HOW?

Q I am running Ubuntu on my computer. I tried using voice and video chat with users of Google Talk but the voice chat feature is not working. I also installed the Empathy IM messenger but I am still not able to video chat with it. Please suggest some solution.

—Ankit Tuteja,
ankit.tuteja02@gmail.com

To enable voice and video chat via Google Talk or Empathy, please install:

- telepathy-gabble
- telepathy-mission-control
- telepathy-stream-engine

Now, configure Empathy using the details of your Gmail account. We are assuming that your video and audio device is configured and working properly.

Hope this solves your problem.

Q I have installed Virtual Box OSE on my system but I am unable to run it, successfully. When I try to open the application, a 'Permissions problem' pop-up window appears with the following message: "You are not a member of the vboxusers group. Please add yourself to this group before starting VirtualBox." I have installed it on my computer system that runs OpenSuse 11.2. My system has 4 GB of RAM and is powered by Intel's Core 2 Duo

processor. Please let me know whether or not my computer configuration is suitable for running Virtual Box.

—Hema Chakravarthy,
hema123.chak@in.com

With the hardware configuration that you have, you can install and run Virtual Box without any issue. The error message is pretty self-explanatory. You need to add the 'User' that is running Virtual Box to the group Virtual Box belongs to. You can do so by using the 'User and Group Management' feature of the application. Hope this helps.

Q I have installed CentOS 5.4 on my server and have been using it without any problems. A few days back I wanted to use Netstat but could not do so as it was not installed on my server. I tried installing it with the following Yum command:

```
#yum install netstat
```

But the command returned an error as stated below:

```
Setting up Install Process
Parsing package install arguments
No package netstat available.
Nothing to do
```

Someone suggested that Netstat belongs to some other package and that I needed to install that package first. Could you please let me know if this suggestion is correct? If so, how can I get to

the name of the package?

—Mohit Chauhan, Mohit_ Chauhan1983@gmail.com

Yes, you can find out the name of the package by running the following command:

```
#yum whatprovides *bin/netstat
```

Matched from:

```
Filename : /bin/netstat
net-tools-1.60-78.el5.i386 : Basic networking tools.
```

The output clearly says that Netstat belongs to the net-tools package.

Q I work on Ubuntu Linux but I do not know whether it is Ubuntu 10.04 or 10.10. I tried the command 'uname -a' but the result did not contain any details about the version. Could you tell me how I can find out which version of Ubuntu I am using?

—Galib Gaurav,
galibgaurav@gmail.com

The command 'uname' is used to print information about the system, such as the kernel version, compile date, architecture, etc. It will not output the OS version name or number. To get the version number you need to run the following in the terminal:

```
#cat /etc/issue

or

#lsb_release -a

or

#cat /etc/lsb_release
```
