

Save Your Data with PhoneGap

The article on PhoneGap Application Development in the June issue of *OSFY* started with setting up the environment for development followed by a simple 'Hello World' app and then moved on to exploring various APIs such as Contacts, Accelerometer and Geolocation. This article covers a lot more...

The APIs we are going to cover in this article are: Storage, Media, Notifications, and Splash Screen.

Storage

This API helps to save the data in the SQLite database and to fetch the same data later. It enables the application to use the data across various HTML pages, i.e., the user can save some data from the first HTML page and then retrieve that at a later point of time.

Usage: Data storage is used in almost all the apps and games. Some basic methods for using storage are:

- `openDatabase()`: This method will open the SQLite database or will create a new one if it doesn't already

exist. It returns a database object that can be used to manipulate data.

- `Transaction()`: This is responsible for database transactions.
- `changeVersion()`: This will change the version with schema updates.
- `executeSql()`: This allows the execution of SQL statements. This method invokes `SQLResultSet` as a callback, which contains properties like `insertId`, `rowsAffected` and `rows` which can be used to display the ID of the inserted row, the rows affected and the rows returned by the executed SQL statement, respectively.
