

Fedora 20 released

Finally, the latest version of Fedora, version 20, has arrived. After much delay, Heisenbug, as it is fondly known as, was released with expanded support for ARM-compatible processors. It also ensures continued heavy development for low-power chips. The latest version of Fedora offers

support for ARMv7hl (hardware floating-point and little endian) devices and also specifies that support for AArch64 is underway. Fedora 20 also takes on RHEL 7 with its 'desperate pronouncements' about the importance of Linux.

According to a statement released by the company, "For 10 years, Fedora has not only led the way as a cutting-edge, open operating system, but the Fedora Project has also served as a paradigm for other open source communities on a global scale."

The Fedora project comes with four board-specific OS images that are capable of running a stable Fedora. The images include the BeagleBone Black, Wandboard, CompuLab TrimSlice, and Calxeda EnergyCore server, apart from Versatile Express for Cortex-A9 and A15 emulation through QEMU virtualisation.

Fedora 20 has been dedicated to Seth Vidal, a tireless and brilliant contributor, who has been the lead developer of Yum and the Fedora update repository. Seth has touched the lives of hundreds of Fedora contributors directly, and millions indirectly by improving the experience of using and updating Fedora.

Mozilla releases Firefox 26 with Java plug-ins

Firefox 26, the latest offering from Mozilla, comes with Java plug-ins, which will put you in control first and then secure your system. Bang on schedule, the latest release of Mozilla Firefox is now available for download.

One of the key features of Firefox 26 is the way Java plug-ins are handled. From now onwards, you will only load Java plug-ins on a 'Click to Play' basis, or when you specifically set a plug-in to 'always run' on certain websites. Prior to this, Firefox automatically loaded Java when a site asked for it.

Mozilla says that this on-demand approach to plug-ins puts users in control, along with providing 'performance, stability, and security benefits.' The new free and open source browser also adds support for H.264 on Linux, a Social Bookmarking feature through the Social API, and a new app manager to help developers test Web apps on Firefox OS.

WordPress 3.8 arrives

Here is some good news for all the WordPress users! WordPress.org has announced the release of WordPress 3.8. The new version comes with a new design, which the company is calling the 'most beautiful update yet.' Those interested can download the new version from WordPress.org/Download. The file size is 6.1 MB.

Motorola makes Moto G components open source

Motorola has put up the open source bits of the Moto G smartphone on its SourceForce page. These include the source files for the device's kernel along with some of the essential and the general public license (GPL) related parts of the Moto G's system.

Using the firmware components that Motorola has made public, developers can build custom firmware for the Moto G smartphone. In fact, third party development is something that is more or less confined to the really high-end smartphones, but given the Moto G's specifications and expected popularity, this one could see developer interest as well. Motorola's aim is to build a smartphone that is affordable, yet does not sacrifice on the specifications and quality.

The Google-owned company has, in fact, received a lot of goodwill after launching the smartphone, with both experts and users appreciating the device. Motorola has even gone to the extent of comparing the device with high-end smartphones from Apple, Samsung and others.
