Explaining the move, the company wrote on its blog, "Some background on this change of order. Normally, this would be the point in time when we turn on CM 11 nightlies. From there, we would spend the next few weeks (or longer) in the nightlies, all the while not allowing you guys (the users) to offer support in the form of bug reports. Taking reports against the constantly changing nightly codebase is too resource intensive, but at the same time, waiting another month to get them going is, in all honesty, wasted time. So, with this change, we are going for the best of both."

Steam OS now available for download!

The first 300 prototypes of Valve's much-awaited Steam Machines have been shipped and, along with it, the Steam OS has been released to the public. As reported earlier, the Steam OS became available for download in the beta mode. The OS will be powering the new gaming consoles (Steam Machines). Valve had earlier announced a December 13 release, advising that only pro-Linux users should download the OS right now.

According to the company, the Steam OS is based on Debian 7 (Wheezy), which has reportedly been optimised by Valve for a living room experience. Further, the GNOME desktop environment is also a pre-installed part of the operating system. And while the OS has been built for gaming purposes, it can still be used as a work PC. Users will simply need to download any relevant software that they need.

The company has also released a set of instructions for those looking to build their own Steam Machines using the Steam OS beta version. In addition, the installation process for the OS is quite simple but you will need to rid your PC of all other operating systems and existing partitions on the PC.

Ubuntu 14.04 to use forked version of GNOME Control Centre

The next iteration of Canonical's premier Ubuntu operating system is going to incorporate some changes to the GNOME Control Centre. According to recent reports, developers from Mark Shuttleworth's Canonical have confirmed that they will fork the Control Centre in the new OS. Currently, Ubuntu uses a utility (System Settings), which is a centralised dashboard that brings together the important configuration options for the desktop.

The version of the GNOME Control Centre currently operating on the Ubuntu OS is known as GNOME 3.6. This is a highly patched version of the original version of the Control Centre. In the new OS, though, Canonical is adding a utility known as the Unity Control Centre, which will be making use of the GNOME Control Centre. So, basically, Canonical is forking the utility into its own Ubuntu version.

Now ownCloud could pose threat to Google Docs, Office 365

Have you heard of the ownCloud Community Edition 6 and its new features? Let us tell you about them. The new feature is called ownCloud Documents and reports say that it could become the ultimate choice for people who use online editing applications often. As you can probably imagine, ownCloud Documents is just like MS Office 365, Google Docs and the Apple iWorks suite. The difference is that ownCloud is a purely open source suite, which supports the ODF format.

From what we understand, ownCloud has definite ties with the KDE community, and its applications use open source technologies that have been developed by KO GmbH. This is the firm that is working on the Krita software that you find in the Calligra Office Suite by KDE. KO GmbH has just a document viewer to offer, while ownCloud offers the entire cloud infrastructure.
