

Five Simple Programming Tips to Enhance Code Security

The very nature of the Internet dictates that no user, Web app or computer is free from security threats. The need for code security can hardly be over emphasised. This article outlines five simple techniques by which code security can be enhanced using the OWASP security guidelines.

The mad rush to finish developing software sometimes hurts software security. Very short development cycles and tight schedules lead to developers neglecting the important aspect of security, which probably gets highlighted during the code review, or even worse, only after the software crashes because of an attack. It is only then that code security gets any attention.

Why can't developers code in such a way that such situations don't arise in the first place, so that the code

they write is secure right from the start? In this article, we explore five simple tips and techniques, which can easily be followed to improve code security immensely. All these tips and techniques are based on OWASP security guidelines. As many of you may be aware, OWASP or the 'Open Web Application Security Project' is a not-for-profit organisation focused on improving software security, and all its guidelines are available under a free and open source licence.
