

Figure 1: WAMP menu

Figure 2: Configuration

folder named **wamp** under the drive you have selected. That folder will have many other folders such as *alias*, *apps*, *bin*, *lang*, *logs*, *scripts*, *tmp*, etc. The important one for developers is the **www** folder, because this is where the projects under development reside. To run your project in WAMP, you need to create a directory for your own project in the **www** directory. You can keep your PHP files in this directory that you have created. Folders other than **www** do have their own significance as explained in the WAMP documentation. To access your project, first check the mode of your WAMP server to see whether it

is online or offline. By default, it is offline after a fresh installation. You need to set it to online mode, by clicking 'Start wampserver' or by double clicking the WAMP server icon found in the task bar. Please refer to Figure 1. The icon colour is red when WAMP is offline. Once started, it first turns orange and then green, when all services are successfully started.

Before we test the installation, let's get a better understanding of a few critical files that need to be tweaked to enable features that can be essential for advanced programmers. The critical files and their installation paths on a Windows machine are mentioned in the accompanying table. As you can see, the three components of WAMP can be easily controlled, configured as well as monitored.

Apache configuration	drive:\wamp\bin\apache\apache-version\conf\httpd.conf
Apache log	drive:\wamp\logs\Access.log
PHP configuration	drive:\wamp\bin\php\php-version\php.ini
PHP log	drive:\wamp\logs\php_error.log
MySQL configuration	drive:\wamp\bin\mysql\mysql-version\my.ini
MySQL log	drive:\wamp\logs\mysql.log
