

The first project

You will get a screen shot that looks like the one in Figure 1. To start a new project you can click on the option 'Create New Project' on the welcome screen or from *File->New->Projects*. Now a new dialogue box should appear (see Figure 2).

Now you have your *main.c* file, which you can modify. For now, it has the normal ‘hello world’ program.

```
#include<stdio.h>
int main()
{ printf("Hello World!");
  return 0;
}
```

 **Note:** The program binaries that you created are available in the project folder.

Debugging

After compilation, if there are any errors, Code::Blocks, like all other IDEs, provides a visual indication on the places where the error has occurred (Please remember that only syntactical errors are displayed).

Figure 2: New project Dialogue Box

Figure 3: Selecting the language

The Code::Blocks debugger has full breakpoint support. It also allows the users to debug their program by using the local function symbol and argument display, user-defined watches, call stack, disassembly, custom memory dump, thread switching, CPU registers, and GNU GDB interface. For debugging with GDB, go to **Menu -> Project -> Build Options** and make sure that the project is compiled with the **-g** (debugging symbols) compiler option on, and the **-s** (strip symbols) option off. This ensures that the executable has debug symbols included. Then you can set toggle.

Some extra features

Tracking modifications

Code::Blocks provides a feature to track modifications within a source and to show a bar in the margin for the changes. Modifications are marked with a yellow change bar, and modifications that are already saved will use a green change bar. You can navigate between your changes via the menu '*Search -> Goto next changed line*' or '*Search -> Goto previous changed line*'. The same functionality is also accessible via the short cuts, Ctrl-F3 and Ctrl-Shift-F3.
