

an elastic and on-demand IaaS. It can also be used to set up an on-premise private cloud behind the organisation's firewall for internal purposes like gaining better control over infrastructure.

CloudStack components

A host is a computer that provides the computing resources such as the CPU, storage, memory, networking, etc., to run the virtual machines. Each host has a hypervisor installed to manage the VMs. As CloudStack is hypervisor agnostic, multiple hypervisor-enabled servers such as a Linux KVM-enabled server, a Citrix XenServer server and an ESXi server can be used.

One or more primary storage is coupled with a cluster that stores the disk volumes for all the VMs running on hosts in that specific cluster.

A cluster consists of one or more hosts and one or more primary storage servers. In other words, a cluster can be considered as a set of XenServer servers or a set of KVM servers.

A CloudStack pod represents a single rack. A CloudStack pod consists of one or more clusters of hosts and one or more primary storage servers. Hosts in the same pod are in the same subnet.

A zone typically corresponds to a single data centre; it is permissible to have multiple zones in a data centre. Pods are contained within zones. Each zone can contain one or more pods. Zones can be public or private.

Secondary storage is shared by all the pods in the zone that stores templates, ISO images and disk volume snapshots.

CloudStack supports two types of networking—basic networking for AWS style networking and advanced

networking for more sophisticated network topologies.

Deployment architecture

A CloudStack installation consists of a management server and the cloud infrastructure. Hosts, storage and IP addresses are managed by the management server. The minimum installation consists of one virtual machine running the CloudStack
