

Virtualisation Mobility

The New Tech Trend

Has the concept of BYOD been successful in the Indian scenario so far?

Does virtualisation affect or facilitate BYOD in any way?

What are your offerings in the virtualisation mobility space?

Soemant Chaudhry,
Director Enterprise Mobility
& Transformation-India
Subcontinent, Citrix

Yes, though it is still prevalent only in pockets, in a few industries. I won't say that people in every vertical are adopting it; but, yes, the concepts have gone in and people have started experimenting. Certain industries or verticals that want to adopt BYOD in a large way include IT, IT&S and BFSI. It offers a flexible working environment.

Yes, in a very positive way. Virtualisation helps to virtualise Windows apps and push them through any operating system. In virtualisation, the end point becomes absolutely agnostic to the operating system. We are the only player that can do a seamless delivery of Android apps, Windows apps, iOS apps, HTML apps and even Web-based apps to any device.

This company started off with application virtualisation and that still continues to be a strong technology for Citrix. It is known as XenApp. We introduced desktop virtualisation a few years back and now it has become mainstream. The technology we have for mobility is XenMobile, which will take any Android, iOS, Web-based or HTML-based application and securely deliver it over your network.

Chris Gacesa,
End Point Sr Product
Manager-APAC, Novell

With the strong adoption trend of mobile devices in India, the distinction between end-points used within an enterprise vs the personal context is blurring rapidly. Users can no longer be prohibited from using their preferred devices for accessing enterprise applications. These devices need to be now managed at an enterprise level, while maintaining the level of usability of these devices. BYOD is here to stay.

We have seen a number of organisations that have chosen a Virtual Desktop Infrastructure (VDI) solution to provide access to their corporate applications. This has primarily been used when either a native 'mobile' (iOS, Android, etc) application or Web based (HTML5) application is not available. We are also seeing a greater use of personal laptop devices in a number of organisations.

Today, Novell provides application isolation or virtual applications, and we provide application streaming via our ZENworks Application Virtualization product. Each method of virtualisation assists customers with managing their mobile needs. Application streaming has been valuable to those organisations that have needed to supply corporate application access to temporary or short term contracting staff.

B S Nagarajan, director,
Systems Engineering,
VMware, India & SAARC

BYOD has gained significant traction in India, especially in the past two years. While we are seeing good traction for BYOD in India, we are also seeing a lot of challenges that CIOs face when implementing BYOD policies. Security and compliance issues, followed by the lack of comprehensive mobile device and information management tools, are creating headaches for CIOs in regulated sectors such as financial services.

Virtualisation means we can run more than one instance of an OS, server or any other computing service in a single device.

More than half of enterprise and SMB organisations are looking to initiate BYOD programmes. Many IT departments are trying to figure out the best approach to manage all of these new end-points and protect corporate data. Virtualisation is one popular option, in this case.

Earlier this year, we unveiled the VMware Horizon Suite, which is a comprehensive platform for workforce mobility that will connect end users to their data, applications and desktops on any device—without sacrificing IT security and control. The VMware Horizon Suite brings together VMware's desktop virtualisation solution and technologies that the company has built from the ground up to support a mobile, collaborative workforce.
