

already know how to work with it, you should learn how to, because you are much more likely to encounter it for some other purpose due to many important components of Ubuntu being made in Python itself. Ubuntu also exposes many important APIs and libraries in Python for developers to use, so it makes sense to work in Python to make this work easier.

Bazaar, on the other hand, is a revision control system that is pretty robust. Since it is also used by Canonical for the development of Ubuntu, easier integration with its ecosystem is obviously one of its advantages. While it is certainly not the most popular, it is used by many developers due to its distributed capabilities and Launchpad integration.

Getting started with Quickly

To get started with installing Quickly, go to <http://developer.ubuntu.com/get-started/> and click on the 'Download Quickly' button. Alternatively, you can run the following command on the development machine:

```
sudo apt-get install quickly quickly-ubuntu-template
```

When Ubuntu completes downloading and installing the Quickly application along with its dependencies, you will be able to use the Quickly workflow to create an Ubuntu application within seconds.

To get started with a basic application template, you can run the following:

```
quickly create ubuntu-application myfirstapp
```

This will create a project directory along with the bazaar repository so that you can start playing around with it. You will then also be able to see a sample window (Figure 1) that says the application has been created and can be edited further in the application designer for GTK+, i.e., Glade.

You can now go to the application's directory, which has been created by Quickly:

```
cd myfirstapp
```

Glade can now be started with the following command:

```
quickly design
```

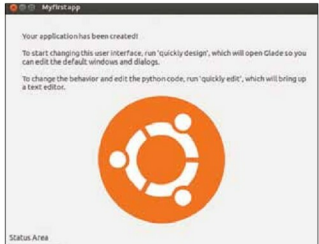

Figure 1: The sample application window opens up when the application is created for the first time

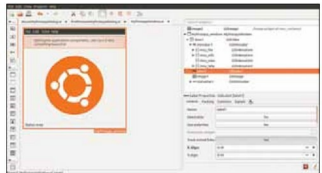

Figure 2: The Glade UI design environment

Glade (Figure 2) will allow you to add new components and change their properties so that you can customise how each new window looks, along with a design view, just like any other IDE that you might have seen.

When the design part for your application is done, you can begin writing some code to actually make it work, and translate those bare bones design components into an integrated application that actually responds to the user's actions in the manner in which you desire. This can be done at the edit stage, with a text editor like Gedit. The following command loads all the files (Figure 3) that can be edited so that the application can be customised to work according to your needs:

EXCELLENT EMAIL INFRASTRUCTURE SOLUTIONS WITH UNMATCHED SERVICE SUPPORT!

- TechnoMail - Enterprise Email Server Anti SPAM, Anti Virus, Email Content Filtering
- Firewall, Internet Access Control Content Filtering, Site Blocking
- Bandwidth Management System
- Managed Email Hosting Solutions
