Large projects

How do you handle a large software project? You break it down into parts, and work on the parts individually. The build/integration process then assembles the project. This process is well tested and is known to scale up and scale out very well. So, why should large literary or documentation projects be any different?

The LaTeX `\input` command lets you include one file into another. If you have a book project, you could keep a base file for the overall framework of the book containing all the typesetting and styling information. You could then include individual chapters that are ready, each in its own `.tex` file that might, in turn, include files for individual sections and stubs for the ones that are not. This lets you concentrate on the content of individual chapters and even farm them out to co-authors. Your book gets built from the top level base file. You can put individual chapters under version control, use GNU/ make and plan labelled releases of your book.

A custom title page

The simplest example of the use of the `\input` command would be the inclusion of a custom title page. If you had a title page like the one below, saved under the name `title-page.tex` you could include it into your main article with a `\input{./title-page.tex}` inserted just after the `\begin{document}` command.

```
% Sample title page template.
% Save this as title-page.tex in your
% current directory.
% Include in main document with command:
% \input{./title-page.tex}
```

```
\begin{titlepage}
\centering

\vspace*{120pt} %vertical space
\Huge{\textsf{\textsc{Your Title}}}
```

```
\vspace{20pt}
```

```
\Large{\textsf{Author Name}}
\vspace{100pt}
```

```
\begin{minipage}{0.4\textwidth}
\begin{flushleft} \Large
Left line 1\\
Left line 2\\
\end{flushleft}
```

```
\end{minipage}
\begin{minipage}{0.4\textwidth}
\begin{flushright} \Large
Right line 1\\
Right line 2\\
\end{flushright}
\end{minipage}
```

```
\will % Fill to bottom of the page
\large\today
\end{titlepage}
```

Creating custom commands

If you issue the same set of commands over and over again or decide to get creative with your LaTeX skills, then you have the option of defining your own custom commands. The simplest kind is akin to macro expansion. For instance, we have been using the word LaTeX quite often in this article. You could define it as follows in the preamble of your `.tex` file `\newcommand {\ltx}{\LaTeX}`. Every time you issue the command `\ltx` it would get expanded to what we have mapped it to. You can use the `\renew` command to overwrite existing commands; use this with caution and only after you have seen some usage examples.

A more useful command might be the one to include figures. Let's define a command with four arguments as follows:

REQD FREELANCER team to complete balance work of a **FOSS WEB APPLICATION** (CentOS, PHP, postgresql and apache server) already **Fully Documented, Screens Data Structures, Menu Completed,**

for one or all of :

- Coding, testing, implementation
- Cloud deployment
- Mobile deployment
- Conversion to different languages
- Conversion of speech to text
- Splitting to several small modules for different level usage

The Web application is a financial management and commerce management product

Work To Be Done At Chennai, Tamil Nadu On **Contract Basis,**
Payment Basis: Lump Sum or **Partnering / Profit Sharing During Maintenance.** Can Also Be Considered.
