

Object Oriented Programming with JavaScript

For many of us, JavaScript is a language that is used to manipulate HTML DOM elements only. But it also has object-oriented characteristics. Read on to learn more about this.

JavaScript helps in adding a dynamic nature to HTML pages. It is based on the ECMAScript, which is the scripting language standardised by Ecma International in the ECMA-262 specification and ISO/IEC 16262. Most modern browsers come with ECMAScript5+.

JavaScript is mainly associated with DOM manipulation. In DOM, the window is the root object of the page and all your other objects like documents, navigation, etc, come under it.

Functions

As we all know, a function is a block of code that can be used again and again. In JavaScript, there is no concept of classes. In the following pages we will look at how a function can also act as a class. A function in JavaScript can act as a simple function as well as a constructor for the object.

Ways of creating functions

A simple function can be created as follows:

```
function info()
{
    console.log("Linux For You is now Open Source For You");
}
```

We can also create the above function by assigning it to a variable:

```
var info=function()
{
    console.log("Linux For You is now Open Source For You");
}
```

In the above case, if you print out the `typeof(info)`, it will give you the function as its result.

There is a special function in JavaScript known as a self-executing function. This will get executed after your full DOM tree gets loaded in the memory. So if you want to
