

Build Your Own Web Page With QForms

QForm is the state-conscious, event-driven object management system for creating Web pages. QForm is the 'C' and 'V' of the MVC architecture of QCubed. It relieves you from typing HTML code for every single element, and dealing with monotonous and repetitive code for handling user actions.

The entire world is moving to the Web. Socket programming is becoming passé for even lower-level programs as JavaScript catches on with JSON, while other Web technologies such as Web sockets promise better results in an increasingly distributed world. We have become habituated to using Web services that promise to be reliable. Facebook, Twitter, GMail, and even WordPress and Drupal, all deliver the content so well that we often forget that the Web is a stateless mess. No machine remembers anything about a previous action, primarily because HTTP does not support states.

What is a state anyway?

When I say stateless, I mean to convey that in most cases, when we log into a Web application, the server does not know the state of the application on the client side. Which elements are being displayed, which ones are hidden, and what can be done on the page—the server knows none of this. To make sure that an invalid request does not cause a security breach, and to assure the right response for every request, a number of methods are in use. In most cases, cookies are used to validate a user's identity and authenticity, and the programmer has to build a system that
