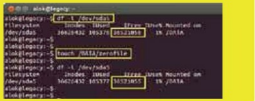
Tips & Tricks

1

You all must have created VM's using KVM or XEN. Ever noticed that whenever you start the libvirt and start creating VM's, the libvirt create a virtual network switch – virbr0. Time to understand what is its purpose. It is a software construct that operates on a host server, to which virtual machines (guests) connect. The network traffic for a guest is directed through this switch. Linux host servers represent a virtual network switch as a network interface. By default, virtual network switches operate in NAT mode.

2

Remember that df command that you have used umpteen times. In case you want to check out the number of used and free inodes available on a file system. You can file command. Just use it with -i switch. Like - df -i /dev/sda5It will show you the total inodes, free inodes and used inodes. To cross check that its actually showing the correct information. I had created a blank file after the first output and it changes the value of inodes free, as anticipated.



3

Here comes a very very very short tip to detect whether the server is behind the firewall or not. What you do next is up to you. :)

Using - nmap -sA x.x.x.x

Here comes the illustration from my machine. If the result comes as "filtered" that means its protected and is behind the firewall and if it comes "unfiltered" ... well you know ... its not behind any firewall.

4

Here are some of the "hot" ways to identify your Linux file system.
