

Arun Kumar, general manager, Red Hat India

"A lot of reports point towards bugs in Java. That doesn't mean Java is inherently insecure. I think security is not just a function of technology, it's a function of process, compliance and how well-structured you are to be able to handle that."

out for all our solutions. So many years after launching, we are comfortable to say that JBoss is one of the best. It is not just about vulnerabilities, but about the ability to respond and fix them quickly when they are found. If you deep dive into the whole scenario, we have two types of users: one set wants ease of use and the other wants a stricter scenario from the beginning. We listened to those needs two years ago and we addressed the security issues right at the very beginning. We have learnt from the past when JBoss was too vulnerable because it was too open. That was the time when we got a hint about this problem

and realised that we needed to make it secure, out of the box.

Arun: Beyond this, the debate on whether open source software is secure or not has not stopped. But the fact remains that organisations do what they want. If indeed what you say is true and if indeed the FUD (Fear, Uncertainty and Doubt) that is spread is true, you won't have stock exchanges deploying this technology. A lot of reports point towards bugs in Java. That doesn't mean Java is inherently insecure. I think security is not just a function of technology, it's a function of process, compliance and how well-structured you are to be able to handle that. JBoss, in particular, has some high level security certifications to its credit from authorities across the globe.

Q OSFY spoke to a developer this morning. He was new to JBoss and he wanted some support and assistance. He tried writing to the community and to the company about it but he did not get any solution. He said he had difficulties with OS GI but since he did not get any response, he had to drop it...

Arun: There is something called the Red Hat Price Subscription,

which is precisely for this purpose. The community exists to give away their innovations and to help build a product. But it is not directly responsible for support. If every developer in this world starts looking at the open source community as a support forum, there will be no development and innovation. Using the community to foster the innovation makes sense. The moment you cross the boundary regarding the extent of support you need, that is when you move from a community product to an enterprise product. Then, that support will come with a subscription model and the upgrades. If I look at it from the India perspective, I think it is fairly immature. We need to understand that the community is not there for support, but it is there to foster innovation and that is how it should be. This is a general problem in this part of the world. People in the other parts of the world are pretty clear that if it is a community product, then don't expect any support. They know that if they want any support, they have to move to an enterprise product. There are companies like us offering support. We are available on call. The experts are there to answer your questions. **END**
