

This article shows you how to make money and have fun with some code, Python and the Internet. It all starts with a four letter acronym, WSGI – a spec that makes it very easy to write applications for the Internet.

The WSGI spec is probably the simplest you'll ever come across. It defines exactly one call interface that your application must implement in order to be a WSGI application. What's more, it doesn't have to be a function—it can be any callable.

The basic skeleton of a WSGI application is as follows:

```
def wsgi_application(environ, start_response):
    start_response("200 OK", [{"Content-Type", "text/
plain"}])
    return ["Hello World"]
```

That's your app. It doesn't do much. It needs all of three lines of code to implement a WSGI application. Of course, it can be quite a headache writing larger

(read 'real-life') applications as a single function; so you can also write a WSGI application like the one shown below:

```
class WSGIApplication(object):
    def __call__(self, environ, start_response):
        start_response("200 OK", [{"Content-Type", "text/
plain"}])
        return ["Hello World"]
```

By implementing a `__call__()` method in a class, you can effectively turn an object into a function (actually, everything in Python is an object—even functions). The class needs to be instantiated into an object, but that object can now behave like a function too.
