

that is similar to a typical Jenkins job. Just create a freestyle Jenkins job and then click the *Configure* link on the left side of the page. In the configuration page, you can see the new options for Android under 'Add build step'. Here you can select the proper actions as you wish for your Android code (Figure 1).

Cloud related plugins

Another interesting type of plugin available for Jenkins is the cloud related JClouds, which adds cloud capabilities to your Jenkins installation. With this plugin, you can launch Jenkins slaves from any cloud provider supported by JClouds. So, if you are running low on hardware at your premises and need a quick status report of your software releases, you can use this plugin and start Jenkins slaves in the cloud to run, build and execute your software.

Plugin installation is the same as discussed earlier. Once installed, configuration is needed. To configure, go to the *Cloud* section in the Jenkins configuration page, click on *Add a new cloud* and then select *Cloud (JCloud)*. In the page that follows, fill in the configuration options. To run your build on the newly configured slave computer, just enable the *Restrict where this project can be run* option in the build configuration page. Enter the label, which you choose for the instance template in the *Label Expression* text field. For more details, you can also check the JCloud plugin page.

Monitoring external jobs

Jenkins also allows you to monitor tasks running outside. Generally, you will need to call the Jenkins plugin from the external job you want to monitor. To get started, you must install plugins like *Monitoring external jobs* and then configure the external job. So, if you want to monitor a cron job on your Linux server, you need to first create a new job with the option *Monitor an external job*. Then add the following code to your cron script:

```
sudo apt-get install jenkins-external-
```
