

The next version of Android will be called KitKat!

Amidst the rumours of Android 5.0, codenamed Key Lime Pie, Android boss Sundar Pichai opened a Pandora's box by revealing Android KitKat. Yes, that's true—you next Android will be Android 4.4 and will be fondly called Android KitKat.

Raising a toast to the success of Android with over 1 billion device activations, Pichai wrote in a Google+ post, "On my return from Asia, I was also thrilled to find this guy waiting to greet me on the front lawn—love the new #Android KitKat statue and can't wait to release the next version of the platform that is as sweet as the candy bar that's one of our team's favourites :)"

Since it is going to be Android 4.4 and not Android 5.0 (Key Lime Pie), we do not expect any major changes in it. The tech experts opine that we should expect only a small upgrade with Android KitKat.

Google releases Chrome 29

Google has announced the release of Chrome version 29 for Windows, Mac, Linux, and Android. To update your system with the latest release, you can use the built-in silent updater of the browser or download it directly from google.com/chrome.

This latest version comes with an enhanced Omnibox suggestion box, profile resetting, along with new apps and extensions APIs.

One of the biggest improvements in the browser is the way Omnibox suggestions work on the desktop now. When Google unveiled it along with the beta, it had said that the changes were "based on the frequency of websites visited, so you'll get more contextually relevant suggestions at the right time."

This basically means that if you are a regular Chrome user, Omnibox will customise its results based on your past usage. But if you are a new user, you will barely notice any difference. The next important change is the option to reset your Chrome profile. Using this, you can spring back your browser to its original state without alternating the themes, bookmarks, or apps. With the latest release, Android has got WebRTC support, offering real-time communication without the need for plugins. This feature has been available on desktop Chrome since version 25 Beta but now it's on Android as well.

Additionally, there are bug fixes, and improvements in stability. In total, Chrome 29 takes care of 25 security issues.

Firefox 24 arrives for Android

Mozilla has officially launched Firefox 24 for Android. The new version comes with a number of new features, improvements and tools that aid easy sharing and support for WebRTC.

Wondering how WebRTC will work on a mobile? Well, with this new feature, Mozilla is now on par with Chrome for Android, as Chrome users have had access to WebRTC in their mobile browsers for a while now. You may not be able to start using this real-time communication protocol right away, but it will surely encourage more developers to write applications for it. Additionally, there is a new 'quickshare' feature in the Firefox Share menu. This means that the new version lets you automate the process of sharing links on Twitter, Facebook or via email.

This new version also supports sharing over NFC, which means you can now bump your phone with your friend's and share easily. It also gets an improved Reader, which lets you read seamlessly. It can switch lights between night and day mode automatically, depending on the ambient light in the room.

The 'shiny' Linux kernel 3.11 arrives!

The 'all shiny and ready to be compiled and loved' Linux kernel 3.11 is here. Making the announcement, Linus Torvalds, the creator of Linux, revealed that the final version of the kernel doesn't have too many changes as compared to the rc7, but it surely has some important bug fixes. Most of the bug fixes have been made in the networking tree, along with some in the file system and the sound features.

In his release announcement, Torvalds regretted missing out on announcing the recently released rc7. Some of the features packed into the
