

execution details, constitute a Jenkins build. In order to get something done, a job has to be created.

Click 'New Job' on the left side of the home page. The 'Build a free-style software project' can be used in most cases, unless you want to build a Maven project or a remote project. The brief description below covers each of the options and will help you decide. Fill in the job name and then select the proper option. On the next page you will have to fill in further details.

Let's look at a free style software project. Although you might select other options, the description is pretty straightforward and will guide you.

As the name suggests, a free style software build is the most flexible way of building source code in Jenkins. Once you arrive at the 'Details' page, the source code management tool to be used can be selected, and Jenkins will take the code from the tool directly. The trigger, which causes the job to start, can also be selected. There is the option of selecting the manner in which to build the code, i.e., using a Windows batch, a Linux shell script, an Ant or a Maven script. After selection, paste the contents of the script to be run. Finally, there is the option of adding additional post build actions. These include sending out email notifications, publishing javadocs, building other projects and so on. After completing the settings, save and apply them. This creates the job that will be listed on the Jenkins home page.

After the job is created, there is nothing more for the developer to do. As and when people check-in their code, Jenkins takes these changes either by polling the SCM or periodically builds the code (based on the trigger). If there is a build breaker, Jenkins will send out email notifications to the people who caused this error.

In the next article in this series, I will try to cover other important features and use cases for Jenkins. **END**
