

Game Development Made Easy with HTML5

With the ever changing business needs and social trends, the importance of online gaming has increased in comparison to any other game format. Currently, HTML5 is the best platform to experiment with, so read on to learn more about it.

Over the past decade, casual online gaming has captured the interest of millions, particularly since the increase in bandwidth speeds, which has been supported by the gadget revolution. People today spend as much time with their gadgets as with humans. Powerful handy gadgets, economical PCs that support remote logins, information sharing via networks, online promotion of brands and Internet access via mobiles have changed the nature of the games being played.

Online games do not require any investment in gaming hardware or consoles. They are accessible from any kind of handy platform, are easy to play and are a refreshing pastime during work breaks. Online games take advantage of the low bandwidth usage and the vast support for multiple platforms to exploit their full potential.

Previously, before online games became so popular, it required considerable man power along with a kind of studio environment and a dedicated team to develop a game. However, today, the development of an online game can be done even by a single person; hence, the cost of development has also reduced.

Online games tend to be highly interactive nowadays and for this developers need to include fluid animations, streaming video and music, and also integrate social network sites. Development and marketing are simple, as there is no sale of hardware involved but just a simple download. Online games do not compete with other forms of gaming -- they are a separate genre.

Currently, HTML5 is the best platform to experiment with, particularly if you are a newcomer to game development or have just shifted to Web-based gaming from any other programming background, due to many of its advantages.

Now, with the help of HTML5, it is possible to embed video and audio, high quality drawings, charts, animation and other rich content without using any plugins and third party programs, as these functions are built into the browser.

Why develop online games?

Factors that motivate developers to create online games include a love for the job, and an increased focus on truly three dimensional and sessions-based multilayer games of many genres.

Different tools, technologies and platforms are required to build and run games for distinct purposes and hardware. But various paths lead to the same destination -- the purpose is to develop and promote powerful online games. The end user does not bother about what is behind the screens, but only wants a great gaming experience.

The changes in game development

Some of the rapid changes taking place in the development and promotion of online browser-based games are:

- New platforms and devices are emerging at a rapid rate, even though the technologies are not standardised so far for Web-based game building or rendering!
- Online game development can happen within a single software platform that can be run on multiple environments.
- Usually the cost of game development is very high, whereas prices of games are coming down due to the gadget revolution. So we need low-price development strategies to build games.
