

In Figure 1, the F column contains formulae with the IF function. The monthly payout is calculated only if the pay-in and payout are the same.

SUMIF function — for conditional totals

I have listed my gold ornaments in a spreadsheet. I have bought most of the gold but some came from

my parents. Because share-trading platforms routinely demand to know my net worth, I need to calculate how much of the gold is my own and how much is not.

Item	Weight	Shop	Date	Source		
Chain	2gm	Kerala	20 January 2020	Own		
Bracelet	7gm	Tanishq	6 December 2021	Parents	Gold from parents	=SUMIF(E2:E12,"=Parents",B2:B12)
Stud	2gm	Bhima	7 February 2021	Own	Gold bought on own	=SUMIF(E2:E12,"=Own",B2:B12)
Coin	8gm	ICICI	12 June 2021	Parents	Total gold	=SUM(B2:B12)
Chain	6gm	Kalyan	16 December 2022	Own		
Ring	2gm	Joy	26 July 2022	Own		

[illegible]

Figure 2: Demo of SUMIF

In Figure 2, the E column shows the source of the gold ornament and the B column gives its weight. Using the SUMIF function, I can add the weights in the B column if the corresponding values in the E column equal a particular type of source. This can be done using the search criterion as either “=Own” or “=Parents”.

VLOOKUP function — for values from a lookup table

I have a list of stocks in my portfolio. Can Excel or Calc show me their worth based on the LTPs (last traded prices)? There are some web services that provide the latest stock quotes but these are all paid services. The National Stock Exchange (NSE) does publish the quotes on its

website. I cannot write a shell script to download it because they use a dynamic link specifically to foil script writers like me.

The only choice is to manually download the market data from the NSE site. From the site menu, choose **MARKET DATA » Equity & SME Market » NIFTY TOTAL MARKET » Download(.csv)**. Open the CSV (comma separated values) file and copy the data to a new worksheet in your Calc file. There will be over 750 rows to copy. (From the first cell, use **Ctrl+Shift+Right** and **Ctrl+Shift+Down** keys to select the whole data.)

Name the worksheet as NSE_MARKET_DATA. For each stock, the trading symbol (code or ID) will be in the A column. The LTP will be in

the F (sixth) column.

In other worksheets, I use a VLOOKUP function wherever I want to display data from the NSE_MARKET_DATA worksheet. (The NSE_MARKET_DATA worksheet is the lookup table.) The first parameter of the function is for the value that I want to look up. The second parameter is the target range in the worksheet containing the lookup table (market data). The third parameter is the column number in the target range that contains the required data corresponding to the looked-up value. The last parameter is set to FALSE or 0 as the market data is not expected to be sorted.

For example, look at this formula in the second row of Figure 3:
