

Data Visualisation Made Easy with Seaborn

Visualisation of large and complex data can help to understand it much better. Python's Seaborn library is an excellent resource for data visualisation and offers a wide range of options.

We are flooded with data today, and so much information and insights can be obtained from it. However, data can always be understood better when we visualise it. Data visualisation can transform complex and big data into easily understandable representations that are also visually attractive, like charts and graphs. Visualisation is also helpful while presenting the data and its findings to stakeholders and business partners, who may not have much technical knowledge. It helps identify anomalies and outliers too.

Python is a widely used programming language in data science and data visualisation. Seaborn is one of the most popular libraries in Python that helps us visualise data easily. It is built on top of matplotlib, which is a lower-level

library for visualisation. We will understand the various functionalities of Seaborn in this article.

We will be using the Google Colab notebook as the IDE here. You can run the same code in any other IDE, like VS Code or PyCharm.

Now let us get started. You can access Google Colab from <http://colab.research.google.com>. Click on the new notebook and open it as shown in Figure 1.

Install the library using the following command:

```
pip install seaborn
```

We will be using a very unusual dataset to explore this library — a dataset about penguins! Sounds interesting, right?
