

Figure 1: Google Colab

character is there or not)
 * - If the given character occurred zero or more times
 + - If the given character occurred one or more times
 {}- The number occurrences of a preceding regex needed to match
 ()- Used to enclose a group of Regex
 \ - To remove the special values of these characters

Let us now use these characters one by one, so that we understand them better.

First, let us use the '.' character. Paste the following code in a cell on the Google Colab notebook we created.

```
import re
string = 'jishnusaaurav12@gmail.com'
match1=re.search(r".",string )
print(match1)
```

Figure 2: Functionality of '.'

Figure 3: Output of []

You can of course use your own string to test and experiment with these characters. In this case, the output would be 'j', because '.' represents any character (as shown in Figure 2).

Looking at the functionality of '[]', we can give a set of characters to match in it.

```
import re
string = 'jishnusaaurav12@gmail.com'
match1=re.search(r"[jc]",string )
print(match1)
```

As you can see in Figure 3, it will give the first occurrence of any of the characters given in [].

The next special characters are '^' and '\$', which represent the beginning and the end of a regular expression. Let us look at an example. Paste the following code:

Figure 4: Beginning and end of a regular expression
