

scalability and reliability of your monitoring practices, consider the following.

- **Scalability:** New Relic One is designed to be highly scalable, enabling monitoring and management of large-scale applications and infrastructure seamlessly.
- **Reliability:** You can leverage New Relic One's alerting and monitoring features to ensure the reliability of your applications. Receive alerts for potential issues before they impact your users, thus maintaining uptime and user satisfaction.
- **Infrastructure monitoring:** New Relic One's infrastructure monitoring capabilities can be used to monitor the performance and health of your infrastructure components such as servers, containers, and databases. Ensure they remain reliable and scalable to support your business needs effectively.

 **Note:** New Relic is a proprietary observability platform. However, you can download a free trial version to explore its features in conjunction with your open source projects. New Relic One integrates with existing open source solutions to provide end-to-end visibility, scalability, and better performance. If the platform meets your project or product requirements, you can then opt for the licensed version to continue using its full capabilities.

In essence, by leveraging New Relic One's robust capabilities and adhering to best practices, organisations can optimise their performance monitoring efforts, unlock valuable insights, and ensure the scalability and reliability of their applications and infrastructure, ultimately driving business success in today's dynamic digital landscape.

Now we are ready with the new dial plan to handle incoming calls.

This dial plan handles internal calls to extensions starting with '10XX'. This is what it does.

Answers the call: The line `exten => _10XX,1,Answer()` answers any call to an extension matching the '10XX' pattern.

Records the call: In the next line `MixMonitor()` is invoked to record the call. It saves the recording to `/home/internal_call/` with a file name containing the date, extension, and unique ID for identification.

Dials the extension: `dial(pjsip/${EXTEN})` routes the call to the specified SIP extension that matches '10XX'.

Hangs up: The call ends with `Hangup()` after the conversation is complete.

To test the working of our simple basic setup of the Asterisk system, dial 1001 and 1002 from the softphone to check the call ring and call recording in `/home/inbound`.

This is a basic introduction to getting started with Asterisk. You can also create your own custom portal with

Asterisk for applications like automated outbound marketing calls or feedback collection, and playing an IVR for answering calls.
