

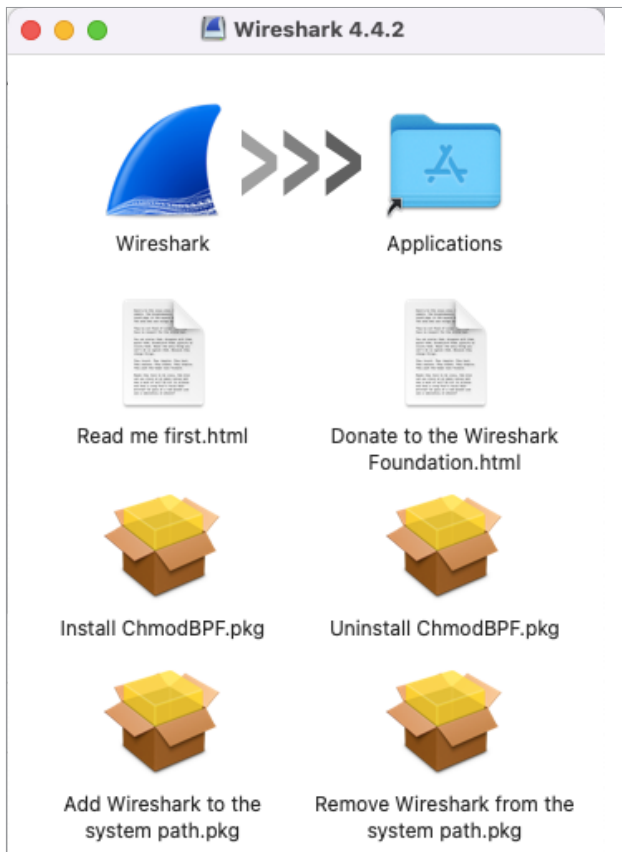

Figure 2: Install Wireshark locally

Let us start by installing this application. You can do this by going to <https://www.wireshark.org/> and downloading the installer for your operating system as shown in Figure 1. If you are using a Mac system, you can follow Figure 2, where you can drag and drop the .dmg file into your applications.

Once the installation is done, the UI should look as shown in Figure 3. It is here that all the magic happens. You can explore all the different options that Wireshark has for your use case.

As stated earlier, in Wireshark, we analyse network packets. A packet is a small unit of data that goes from the source to the destination. If you look at the top left corner of this UI, you will find the *Start* and *Stop* buttons. The Wireshark logo button is the *Start* button and the red square is the *Stop* button, as shown in Figure 4.

You can see that you have different options to choose from to analyse the packets — you can choose Wi-Fi or Ethernet if you are connected to one. Once that is done, you can click the *Start* button, and you will see all the packets of data coming to and going from your machine as shown in Figure 5.

Now click the *Stop* button and see how many packets were sent in this duration. After this, you can click on each packet and analyse what the packet is, what protocol it has, and more as shown in Figure 6. In my case you can see that it is a packet using UDP protocol. You can also see the source destination and the other details as needed. You can save this capture for further analysis later as a .pcapng file as shown in Figure 7.
