

CIMB Bank Malaysia's innovative approach exemplifies the power of open source solutions in driving growth and resilience, setting a benchmark for organisations across the APAC region. Through this recognition, Red Hat underscores the critical role of open source in empowering businesses to unlock their next opportunities.

Red Hat launches Ansible Automation Platform Service on AWS

Red Hat, Inc., has announced the general availability of the Red Hat Ansible Automation Platform Service on Amazon Web Services (AWS) as a managed offering available through AWS Marketplace. This new service simplifies the management of hybrid cloud infrastructure, enabling customers to streamline complex and error-prone operations while offering flexibility in deploying Red Hat's open technologies on-premises or in AWS environments.

Ansible Automation Platform Service on AWS allows IT teams to begin automating processes from day one, providing a cloud-optimised solution that eliminates the need for learning new tools or integrating additional technologies. Designed for customers with varying levels of automation experience, this service enables faster, more efficient automation deployment at scale.

The platform integrates seamlessly with AWS billing, offering customers a unified view of costs while contributing to committed spend agreements with AWS. Whether cloud-native or pursuing a cloud-first strategy, customers can choose

between managed and self-managed options for the Ansible Automation Platform on AWS, ensuring a tailored solution to meet their unique needs.

The Red Hat-managed offering also enables Red Hat

services partners to accelerate their customers' automation journey through the rapid deployment and development of Ansible Playbooks.

Sathish Balakrishnan, vice president and general manager, Ansible, Red Hat, said: "Businesses can only achieve their goals if automation is viewed as essential to the enterprise IT strategy. But to perform automation as a true, mission-critical IT strategy, there needs to be a capable and broadly available platform that unifies and propels continuous innovation. Red Hat Ansible Automation Platform as a managed offering in AWS Marketplace helps us to further equip our customers with the right technology at the right time, enabling them to exceed their goals and expand what's possible with mission-critical automation."

RHEL AI is now available on Azure Marketplace

Red Hat, Inc., has announced an expanded partnership with Microsoft to enhance artificial intelligence (AI) and generative AI (gen AI) deployments in the cloud. As part of this collaboration, Red Hat Enterprise Linux AI (RHEL AI) is now available on Azure Marketplace as both an optimised, validated foundation model platform and a bring-your-own-subscription (BYOS) offering, designed to run seamlessly in Microsoft Azure environments.

"Red Hat Enterprise Linux AI on Microsoft Azure empowers organisations to scale gen AI deployments with greater confidence and flexibility to act quickly on the opportunities that AI presents for their business today, and paving the way for

Kubernetes v1.32 adds a strict CPU reservation option for the CPU Manager static policy

Kubernetes v1.32, after years of community discussion, has introduced a strict-cpu-reservation option for the CPU Manager static policy. This feature is currently in alpha, with the associated policy hidden by default. You can only use the policy if you explicitly enable the alpha behaviour in your cluster.

The CPU Manager static policy is used to reduce latency or improve performance. The reservedSystemCPUs defines an explicit CPU set for OS system daemons and Kubernetes system daemons. If you want to protect your system daemons and interrupt processing, the obvious way is to use the reservedSystemCPUs option.

However, until the Kubernetes v1.32 release, this isolation was only implemented for guaranteed pods that made requests for a whole number of CPUs. At pod admission time, the kubelet only compares the CPU requests against the allocatable CPUs. In Kubernetes, limits can be higher than the requests; the previous implementation allowed burstable and best-effort pods to use up the capacity of reservedSystemCPUs, which could then starve host OS services of CPUs. The existing behaviour also made benchmarking (for both infrastructure and workloads) results inaccurate.

When this new strict-cpu-reservation policy option is enabled, the CPU Manager static policy will not allow any workload to use the reserved system CPU cores.

Strict CPU reservation is critical for Telco/NFV use cases. It is also a prerequisite for enabling the all-in-one type of deployments where workloads are placed on nodes serving combined control+worker+storage roles.
