

IoT Services Offered by Microsoft Azure: An Overview

Discover the range of services offered by Microsoft's Azure platform for the Internet of Things, including IoT Hub and Digital Twins.

The Internet of Things (IoT) has pervaded homes and organisations, connecting devices to enhance daily life and productivity, respectively. IoT architecture is based on three major components.

Edge client: Collates data from connected devices and sends to the gateway.

Gateway: Validates, identifies and classifies data, and forwards it to the cloud platform for storage and processing.

Cloud: Receives data blocks from the gateway, stores them, and transfers them for processing.

Building security into IoT architecture

Since many third party and native services are involved in IoT architecture,

The Internet of Everything (IoE) is the amalgamation of IoT (Internet of

Things), IoD (Internet of Digital) and IoH (Internet of Humans) to create a connection between people, smart devices and organisations. Internet of Digital is the group of data service applications that handle social networks, media services, analytics on data, and cloud platforms (simply termed as SMAC). Internet of Humans deals with smart devices that interact with humans (like smart bands and medical monitors) to monitor and collect various datasets from human interaction. These devices can be used for remote patient monitoring using cloud-based platforms or remote health advisory solutions through contact centre AI services.

Internet of Everything (IoE) is an emerging trend in new age architecture and requires costly infrastructure, but is touted to become popular soon.
