

Moreover, IPFire 2.29 Core Update 186 has integrated Spamhaus EDROP support into DROP, replacing Alienvault. This change aims to bolster network security. The update also includes Linux Landlock support in the Suricata open source network analysis and threat detection software, which helps protect IPFire installations from unauthorised file system access.

“Currently this has been implemented to test out what benefits IPFire could draw from this new design of a file system. It enables compression of all data it holds and allows to create snapshots which might become useful for the development process and enable easier rollbacks,” said IPFire developer Michael Tremer.

Other significant changes include a patched bridge between Unbound and DHCP Leases, which prevents unnecessary reloads of the Unbound DNS resolver, leading to a more efficient operation. The boot process has been made quieter by removing unnecessary warnings, enhancing the startup experience.

Additionally, the update has seen the removal of the sslh add-on and the Icinga open source computer system and network monitoring application due to a lack of interest from IPFire users.

Under the hood, IPFire 2.29 Core Update 186 includes updates to a variety of packages including Apache2 2.4.59, BIND 9.16.49, kmod 32, libhttp 0.5.48, SQLite 3.45.3, and squid, which ensures enhanced security and performance.

openSUSE Leap 15.6 is available for download

The openSUSE Project has officially released openSUSE Leap 15.6, marking the latest stable iteration of this openSUSE variant tailored for those who prefer a conservative and thoroughly tested operating system.

Built upon SUSE Linux Enterprise 15 Service Pack 6 (SP6), openSUSE Leap 15.6 arrives a year after its predecessor, Leap 15.5, and operates on the Linux 6.4 kernel series. The release includes preinstalled images featuring several popular desktop environments — KDE Plasma 5.27.11 LTS, GNOME 45, and Xfce 4.18 — catering to a variety of user preferences.

A significant addition to openSUSE Leap 15.6 is the integration of the Cockpit package, which enhances system and container management capabilities. Cockpit provides system administrators with a web-based interface that combines advanced operations with user-friendly accessibility, making it easier to manage complex tasks.

openSUSE Leap 15.6 boasts an array of updated GNU/Linux technologies that enhance its performance and capabilities. These updates include Python 3.11, Qt 5.15.12 LTS, KDE Frameworks 5.115, OpenSSL 3.1, MariaDB 10.11.6, PostgreSQL 16, Redis 7.2, PHP 8.2, Node.js 20, PulseAudio 17.0, PipeWire 1.0.4, DPDK 22.11, Open vSwitch 3.1, OVN 23.03, Xen

4.18, KVM 8.2.2, virt-manager 4.1, and libvirt 10.0. These technologies provide the backbone for a robust, secure, and highly functional operating system suited for diverse computing environments.

“The transition to Python 3.11 in Leap 15.6 involves the removal of many unmaintained Python packages. This move ensures that the system remains secure and up-to-date with the latest Python features and improvements, benefiting developers and users alike,” noted the team at openSUSE.

You can download openSUSE Leap 15.6 from the official website, where it is available as live ISO images preinstalled with popular desktop environments such as KDE Plasma, GNOME, and Xfce. A Rescue edition and offline installation images are also available.

openSUSE Leap 15.6 supports a wide range of hardware platforms. It is compatible with 64-bit desktops, PowerPC (ppc64le) servers, UEFI ARM 64-bit (AArch64) desktops, laptops, single-board computers (SBCs), and servers, as well as IBM System z and LinuxONE (s390x) servers. For those interested in virtualisation, virtual machine images are also available for download, providing a convenient option for deploying openSUSE Leap in a virtualised environment.
