

HydraChain: Simplifying Blockchain Technology

Blockchain technology has revolutionised the way we transact with and secure data. However, its complexity and scalability issues have posed challenges for widespread adoption. Enter HydraChain, a groundbreaking solution that aims to simplify blockchain technology and address its limitations.

The Hydra blockchain is a hybrid that uses the transaction model of Bitcoin and employs the powerful virtual machine of Ethereum. It is based on the Bitcoin Core, Ethereum and Qtum. It is also called HydraChain or simply Hydra (the Greek mythological beast).

Some crypto stakeholders believe Hydra's unique mechanisms will spear it to overtake Ethereum in the long run. Its scalability of up to 540 transactions per second is an important feature.

Understanding the complexity of blockchain

Hydra was launched in late 2020 and has since grown by more than 1000% in price. The chain quickly established a strong node infrastructure and now has more than 500 validators across the globe.

The Hydra blockchain supports Turing-complete smart contract functionality, which allows the execution of decentralised applications on a chain. Tokens and DApps

(decentralised applications) built on Hydra profit from gas royalty of transaction fees (passive income). Every project contributes to the transactional economy, increases the rate at which Hydra chains are burnt, and helps to grow the overall size of the ecosystem.

The HydraChain fills an important gap at the protocol level by enabling a refund of transaction fees to token creators. The mechanism rewards project owners by giving a share of
