

For example:

```
car = {
    "brand": "Ford",
    "model": "Mustang",
    "year": 1964
}
x = car.items()
print(x)
car["model"] = "Figo"
print(x)
Output:
dict_items([('brand', 'Ford'), ('model', 'Mustang'), ('year', 1964)])
dict_items([('brand', 'Ford'), ('model', 'Figo'), ('year', 1964)])
```

Keys

The `keys()` method returns a view object of all the available first level keys in the dictionary. The view object contains the keys of the dictionary as a list and will reflect any changes done to the dictionary. For example:

```
car = {
    "brand": "Ford",
    "model": "Mustang",
    "year": 1964,
    "details": {
        "wheels": 4,
        "doors": 2,
    }
}
x = car.keys()
print(x)

Output:
dict_keys(['brand', 'model', 'year', 'details'])
```

Values

`values()` is an inbuilt method in Python that returns a view object. The view object contains the values of the dictionary as a list and will reflect any changes done to the dictionary. Here's an example:

```
car = {
    "brand": "Ford",
    "model": "Mustang",
    "year": 1964,
    "details": {
        "wheels": 4,
        "doors": 2,
    }
}
```

```
x = car.values()
print(x)
```

Output:

```
dict_values(['Ford', 'Mustang', 1964, {'wheels': 4, 'doors': 2}])
```

Filters

We will just explore some sample examples here, but a very good blog at <https://learnpython.com/blog/filter-dictionary-in-python/> details many more possibilities.

To filter dict with only partial matching values from dictionary, use the following code:

```
cars = {
    "ford_figo": 1990,
    "ford_focus": 1991,
    "ford_feista": 1992
}
print("Before drop of the column", cars)
filter_str = "ford_feista"
cars = dict(filter(lambda item: filter_str not in item[0], cars.items()))
print("After drop of the column", cars)
```

Output:

```
Before drop of the column {'ford_figo': 1990, 'ford_focus': 1991, 'ford_feista': 1992}
After drop of the column {'ford_figo': 1990, 'ford_focus': 1991}
```

Filter and save empty values in dict as follows:

```
cars = {
    "ford_figo": 1990,
    "ford_focus": 1991,
    "ford_feista": 1992,
    "ford_dummy": 0
}
print("Before drop of the column", cars)
cars = dict(filter(lambda item: not item[1], cars.items()))
print("After drop of the column", cars)
```

Output:

```
Before drop of the column {'ford_figo': 1990, 'ford_focus': 1991, 'ford_feista': 1992, 'ford_dummy': 0}
After drop of the column {'ford_dummy': 0}
```

Delete

The following example gives the code to delete the keys and the dictionary.

```
dict1 = {'a': 1, 'b': 2, 'c': 3, 'd': 4, 'e': 5}
```
