

Apache Software Foundation releases Apache Sling 13

The Apache Software Foundation (ASF), the all-volunteer organisation behind over 320 active open source projects, has officially announced the release of Apache Sling 13. This latest version enhances its reputation as a powerful framework for RESTful web applications, offering developers a highly extensible content tree and resource-driven request processing. Designed to serve a diverse range of use cases, Sling 13 provides the foundation for everything from lightweight blogging platforms to large-scale enterprise content management systems.

Apache Sling simplifies development by mapping HTTP request URLs directly to content resources, utilising path, extension, and selector-based routing. This approach promotes meaningful URLs and enables resource-driven request processing, making applications more intuitive and efficient. Additionally, Sling's modular architecture allows developers to configure their server environments with only the necessary components, optimising performance and scalability.

“Apache Sling is extremely modular, allowing users to build anything from small microservice applications to very large enterprise applications,” said Robert Munteanu, Apache Sling PMC Chair. “Sling 13 gives users many performance enhancements and efficiencies, including greater security overall. We are very proud of the community’s dedication and hard work to make this release available to users.”

With Apache Sling 13, developers gain greater flexibility in building modern web applications while leveraging the reliability and innovation of an ASF project.

“Users installing openSUSE Tumbleweed via the ISO image will see SELinux in enforcing mode as the default option in the installer. If the user prefers to use AppArmor instead of SELinux, they are able to change the selection to AppArmor manually in the installer,” said Cathy Hu, SELinux security engineer, on behalf of the openSUSE security team.

Additionally, openSUSE announced that the minimal VM image for openSUSE Tumbleweed will ship with SELinux in enforcing mode. For users looking to migrate from AppArmor to SELinux, a step-by-step guide will be available on the openSUSE Wiki.

openSUSE also clarified that this change does not impact the stable openSUSE Leap 15.x series, which will continue using AppArmor as the default mandatory access control (MAC) system.

KDE Plasma 6.3.1 released with Plasma Discover improvements

The KDE Project has released KDE Plasma 6.3.1, the first maintenance update for the KDE Plasma 6.3 desktop environment, bringing an initial batch of bug fixes and improvements.

This update enhances the Plasma Discover package manager by making the updates list case-insensitively sorted and restoring search results for the BBC Weather provider in the weather widget. It also improves the Welcome Center by ensuring it remembers its window size on Wayland and position on X11 across launches.

Additionally, KDE Plasma 6.3.1 refines search results for the new DWD weather provider in the Weather Report widget and improves the reliability of the desktop

trashcan icon, ensuring it updates its appearance correctly based on whether files are in the trash.

Numerous bug fixes are included, such as resolving a regression that caused the KWin window and composite manager to crash in X11 when hotplugging

or switching HDMI screens. KDE developers are encouraging X11 users to try the Wayland session, as X11 now receives minimal testing.

Other fixes address two intermittent crashes in the portal-based screen chooser dialog, KWin crashes after hotplugging a Thunderbolt dock, and certain Qt-based apps crashing on launch when using the Breeze style. The Clipboard widget also received a fix for an issue causing overlapping items in the list view.

Additional fixes include resolving Plasma crashes when clicking the Networks icon in the system tray, restoring immediate visibility of keyboard brightness controls on certain laptops, and preventing the Energy page in Info Center from vibrating at certain window sizes.

Visual improvements have been made to the Digital Clock widget’s new bar separator between the date and time and the Kickoff application launcher’s panel button when using non-square images.

KDE Plasma 6.3.1 will soon be available in the stable software repositories of various GNU/Linux distributions. For a full list of changes, refer to the official changelog.

Red Hat and neoleap collaborate for modernising applications

Red Hat, Inc., has partnered with neoleap, a subsidiary of Alrajhi Bank and a leading digital financial services provider in Saudi Arabia, to develop a new platform that accelerates innovation while enhancing security.
