

anyone, improving their functionality. Another example could be a chart used in a dashboard for metrics.

In many development scenarios, developers prefer to use existing open source resources rather than writing code from scratch. This is where our components come into play. We develop them for our use initially, but they are structured to either stand alone or be bundled with others to assemble an application quickly. By offering these components, we enable developers to pick and choose what they need for their projects, whether it's a single piece or multiple pieces that can be combined. This flexibility and modularity accelerate development processes, making it easier for startups and other entities to quickly deploy functional and practical software solutions.

Q: What are your target systems when it comes to application?

A: We target both customer-facing and backend systems. For customer-facing applications, this includes mobile and web apps, where the user directly interacts with the software. On the backend, our focus extends to cloud services and middleware, which, though not directly visible to the customer, are crucial for the smooth functioning of the front-end applications. In particular, we specialise in building components that enhance the performance and functionality of these systems. For example, in a video rendering application, we might develop a component that accelerates how the video is processed or how data is pulled from the backend system to the user interface. Our approach aligns with the open source philosophy of not building everything from scratch. We focus on developing and sourcing components to speed up the development process.

Q: Where do you generate your revenue from?

A: Our revenue model is based on professional services provided for custom project development, which may involve a mix of open source and proprietary components, depending on the client's requirements and the nature of the project. While we build a range of software solutions, only some things are open sourced. We work on projects for clients where some components are proprietary to those clients. However, when engaging with clients, we make it clear from the outset which parts of our technology stack are open source. We emphasise that these open source components are non-negotiable and remain non-proprietary. The proprietary aspects of the solutions we develop are specific to each project and are where we generate revenue. These projects often involve building critical solutions tailored to the client's needs, and we charge professional service fees for this development work.

Q: What are the target markets for your products?

A: We decide this based on the criticality of handling — what the product is for and how specific it is to a client's business. It becomes proprietary if we create something that uses a client's unique knowledge or is specific to their business. However, if we develop common parts that are useful for many clients or the whole industry, we open source them. So, things that are special secrets for a client's business stay proprietary, but things that can be helpful to many get shared as open sourced.

Q: Who is the target market sector for your products?

A: We target anyone who needs a solution or has a problem to solve. This includes many areas, such as brand development, marketing strategies, technology solutions, mission-critical applications, cloud

Sunil Kalkunte, Engineering Leader and Country Head, Code and Theory, India

services, and data management.

Q: What is your objective for participating in the Open Source India (OSI) conference?

A: As a technology-first creative agency, we recognise the role of open source in the tech industry. We started this journey three years ago to benefit from open source resources and contribute back to the community. As a net contributor, we're focused on giving back as much as we use from the open source community to develop our software and serve our customers. Our presence at the OSI conference is an opportunity to share our experiences and contributions in the industry, particularly in the open source domain. It serves as a platform to increase awareness of Code and Theory, which is the only agency with 50% engineers and 50% creatives at scale, enhancing our brand recognition in the market.
