

How Do Docker Hub and GitHub Actions Streamline the Continuous Deployment Workflow?

Code it, commit it, forget it! GitHub Actions and Docker Hub ensure your deployment hits production faster than you can say ‘push’.

In software development, speed and efficiency are everything. Continuous deployment, a practice that automatically deploys new code changes to production, has become a cornerstone of modern development methodologies. To streamline this process, developers often turn to powerful tools like Docker Hub and GitHub Actions.

Let's explore how Docker Hub and GitHub Actions work together to streamline the continuous deployment workflow.

What is Docker Hub?

Docker Hub is a cloud-based repository that serves as a central location for storing, managing, and distributing Docker images. Think of it as a library for pre-packaged

applications where you can find images created by various individuals and organisations.

Docker images play a crucial role in continuous deployment (CD) workflows. They provide a consistent and isolated environment for your application, ensuring that it runs the same way regardless of the underlying infrastructure. This standardisation simplifies the deployment process and reduces the risk of errors.

What is GitHub Actions?

GitHub Actions is a CI/CD automation tool built into GitHub. It allows you to automate various tasks within your software development workflow, such as building, testing, and
